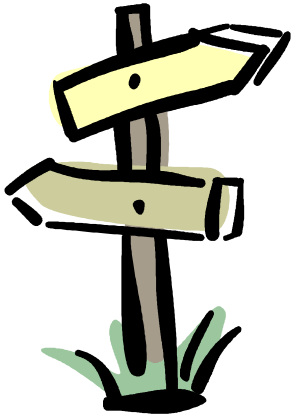
Fingerprint recognition

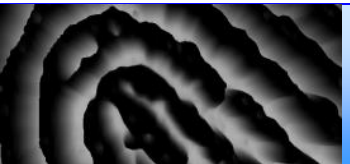
State-of-the-art and new directions

Outline

- State-of-the-art
  - Image acquisition
  - Feature extraction
  - Matching approaches
  - Performance evaluation

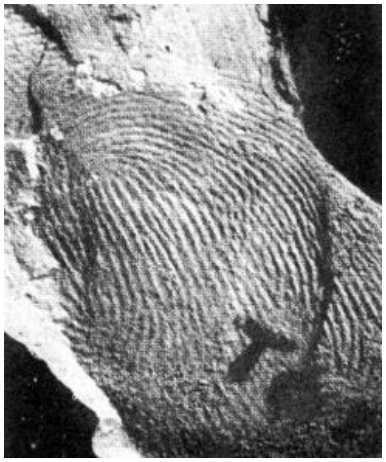


- Open issues
  - Automatic processing of latent fingerprints
  - Fake finger detection (PAD)
  - Fingerphoto recognition
  - Predicting performance in large-scale systems
  - Double identity fingerprints

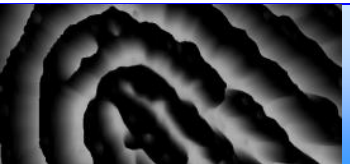


Why fingerprints?

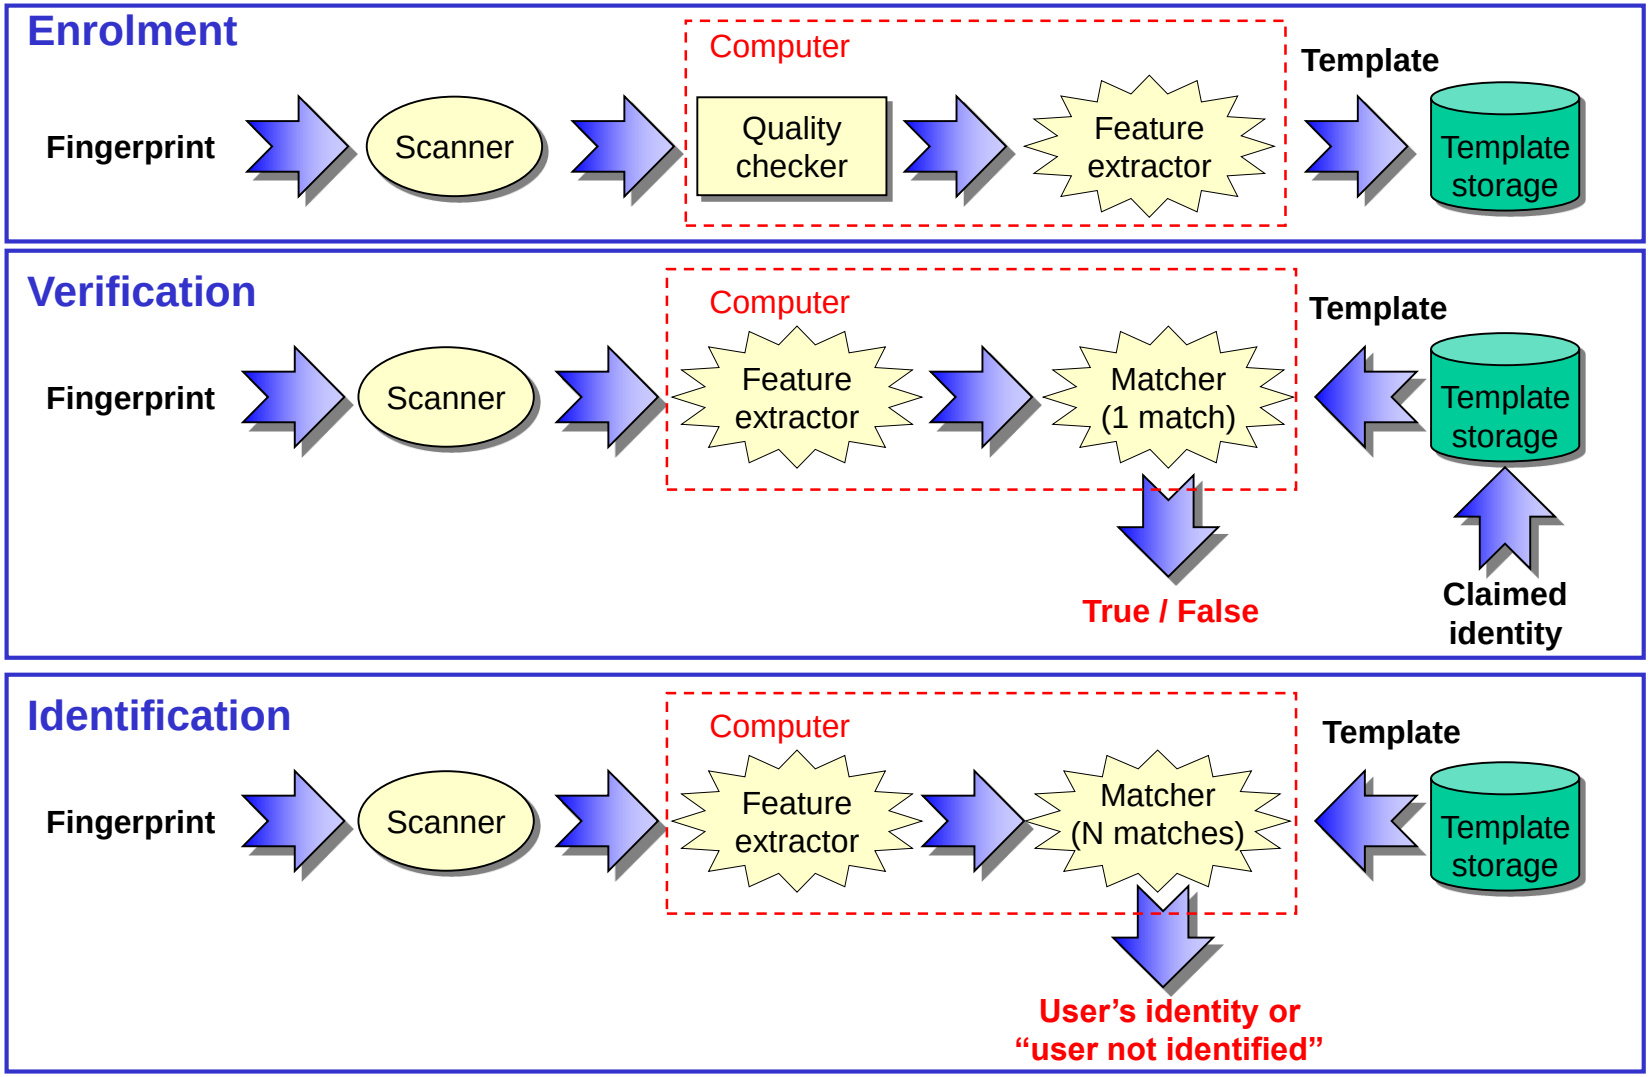
- Highly distinctive and unique
- Do not change during the lifetime of a person
- Publicly accepted as reliable (evidence in a court of law)
- Identical twins have different fingerprints



An impression on a Palestinian lamp (400 B.C.)



Fingerprint recognition system



Fingerprint acquisition

- Off-line acquisition
  - Ink technique
  - Latent fingerprints

- On-line acquisition
  - Optical sensors
  - Silicon-based sensors
  - Ultrasound
  - Fingerphoto
  - Emerging (OCT, Organic)

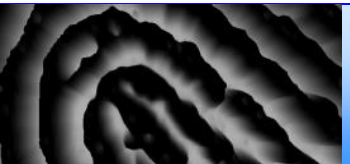
Fake Fingerprints

The idea of using fake fingerprints to fool biometric recognition is not new

Diamonds are Forever
(1971)

Bond goes undercover as Peter Franks, a diamond smuggler...



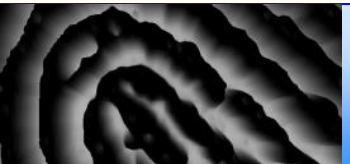
Fake detection

- Making a fake finger is not easy, but with the right knowledge and the appropriate materials ...
  - Much more easy with cooperation of the user
  - Typical materials:
    - Gelatin, Silicone, Latex.

Gelatine Finger

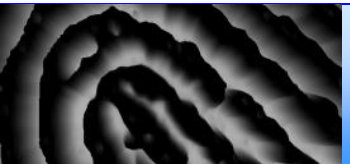
Silicone Finger

Latex Finger



Fake detection (2)

- The potential weakness of commercial fingerprint scanners has been highlighted in some works:
  - Fingerprint recognition–don't get your fingers burned [Van der Putte, Keuning, 2000]
  - Impact of artificial "gummy" fingers on fingerprint systems [Matsumoto, 2002]
  - …
  - Fake Finger Detection by Skin Distortion Analysis [A. Antonelli, R. Cappelli, D. Maio and D. Maltoni - IEEE Transactions on Information Forensics and Security, 2006]
- Possible measures
  - Intrinsic properties of a live person
    - Physical (e.g. elasticity), Electrical (e.g. resistance), Visual (e.g. color), …
  - Signals generated involuntarily
    - Pulsation, Blood pressure, Perspiration, …
  - Voluntary/involuntary response to stimuli
- Technology still not mature enough …
  - Refer to LivDet 2009, 2011, 2013, 2015, 2017 (Fingerprint Liveness Detection Competition) for independent evaluations



Fake finger detection by distortion analysis

The user is required to place a finger onto the scanner surface and to apply some pressure while rotating the finger

Real finger

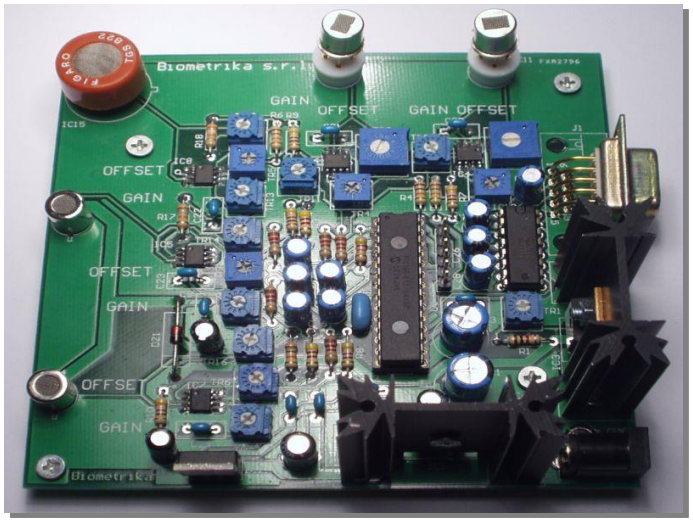
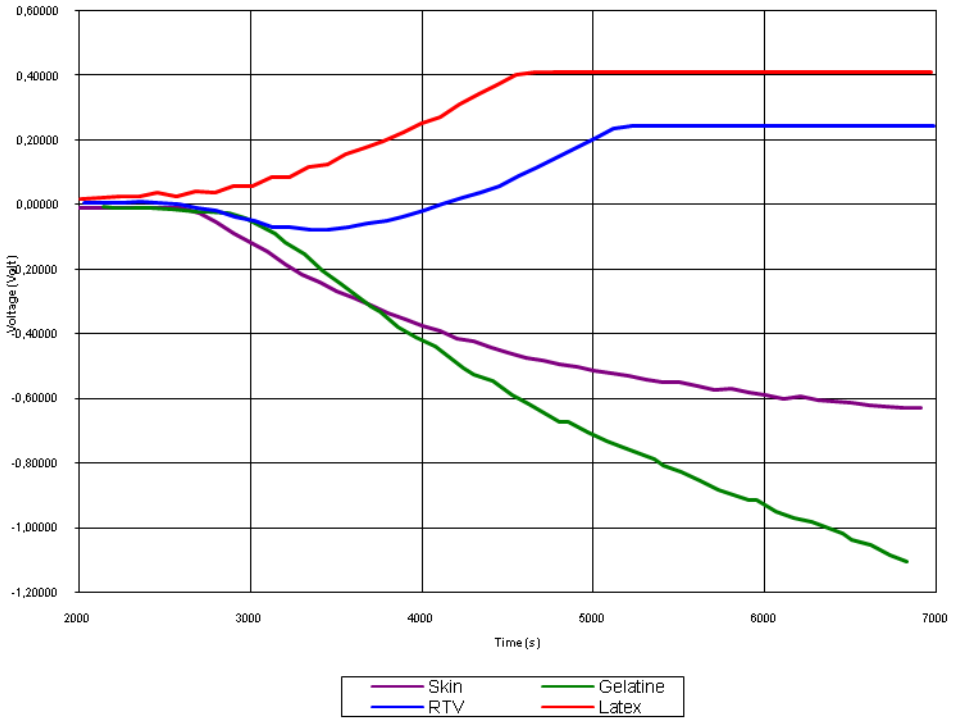
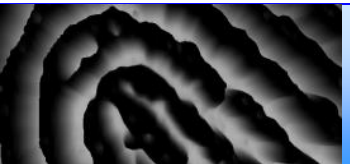
DistortionCode

Fake finger detection by odor analysis





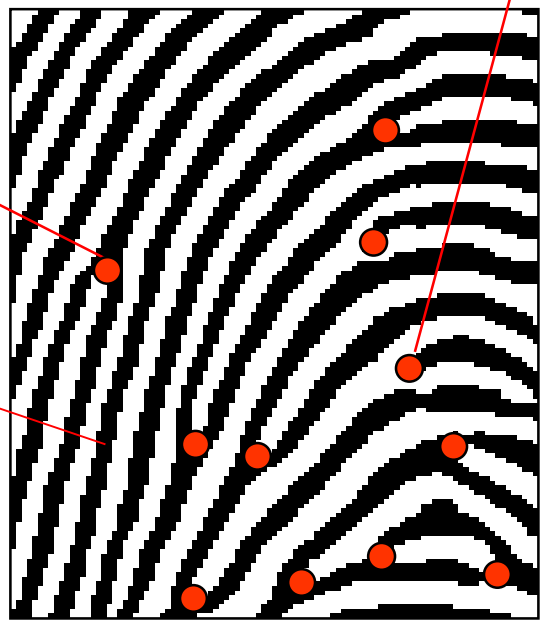
- The idea:
  - Using one or more odor sensors (*electronic noses*) to detect materials usually adopted to make fake fingers
    - Electronic nose: array of chemical sensors designed to detect and discriminate complex odors



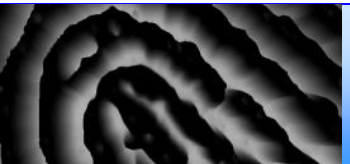
Fingerprint anatomy (1)

A fingerprint is composed of a set of lines (ridge lines), which mainly flow parallel, making a pattern (ridge pattern)

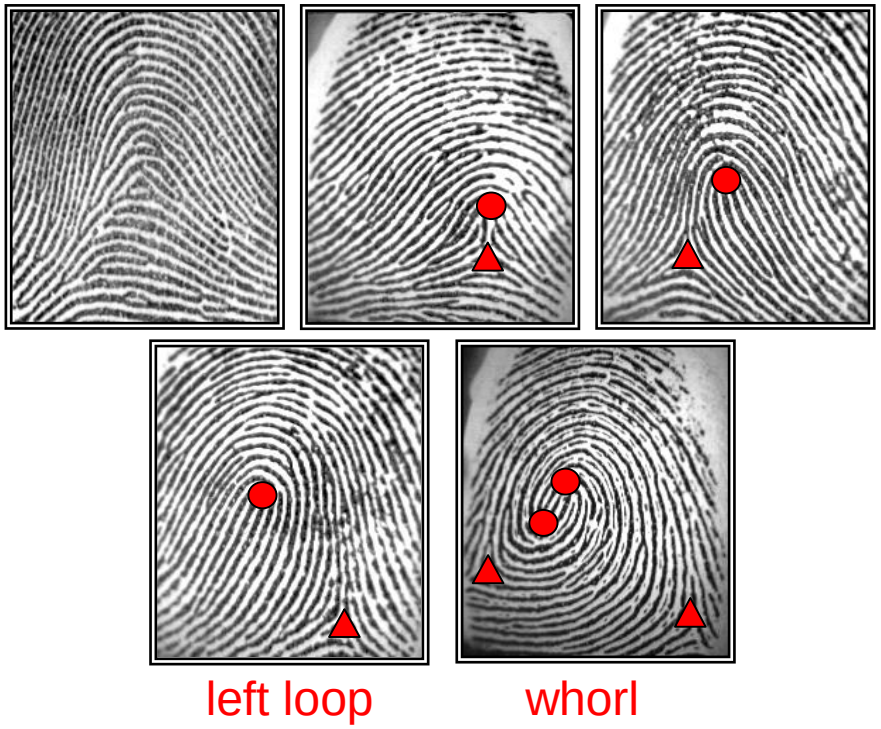
Sometimes the ridge lines produce local macro-singularities, called whorl (O), loop (U) and delta (Δ)



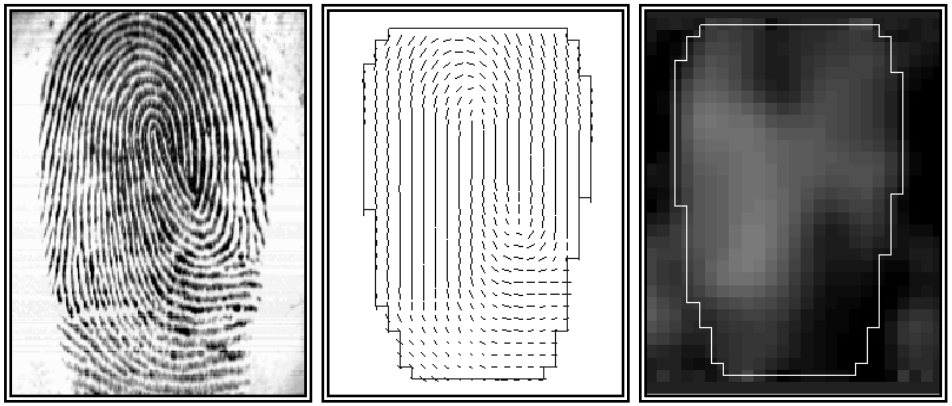
The minutiae, or Galton's characteristics, are determined by the termination or the bifurcation of the ridge lines



Fingerprint anatomy (2)

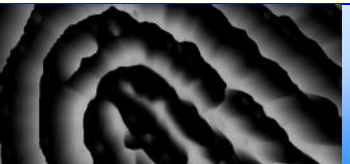


The five main fingerprint classes



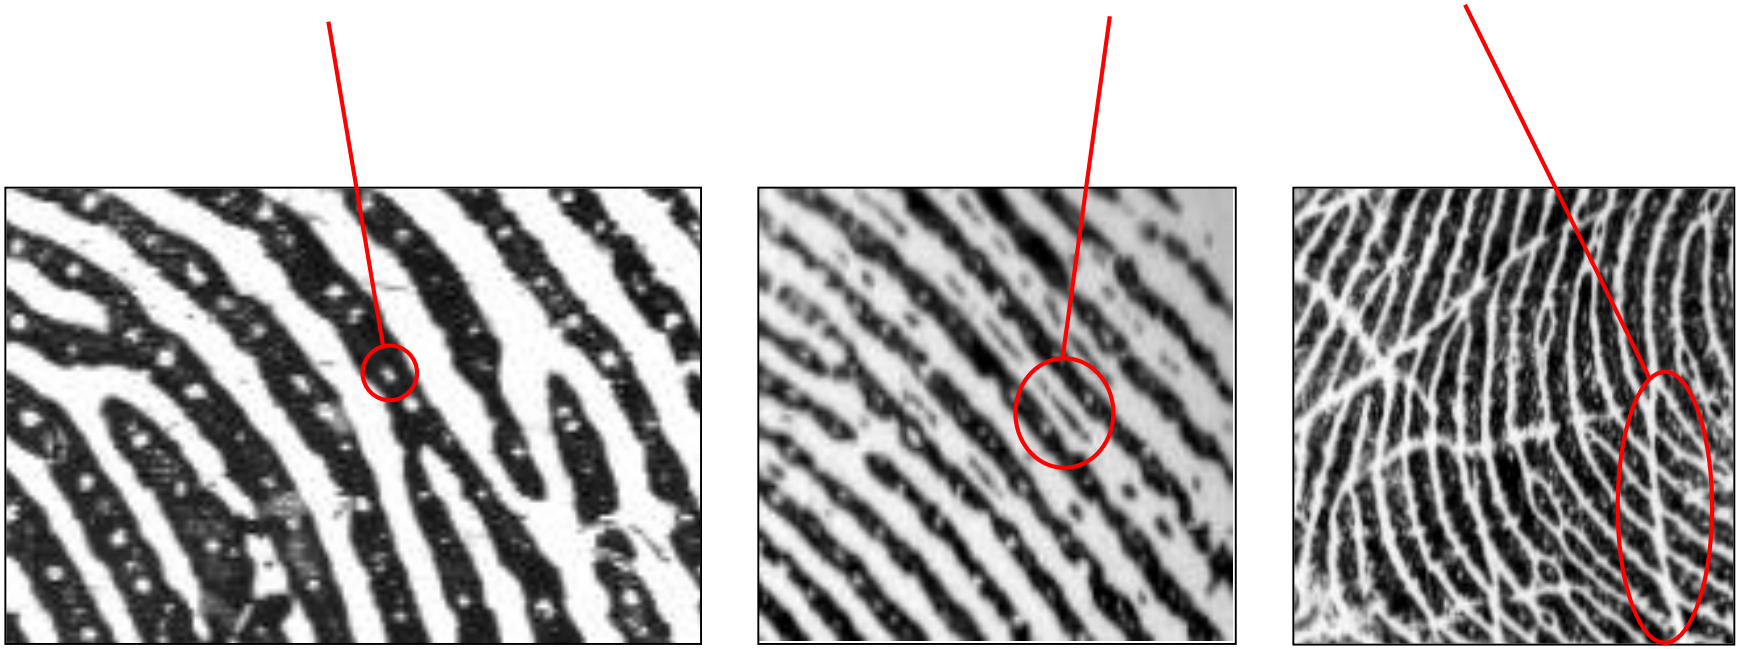
fingerprint **orientation image** **frequency image**

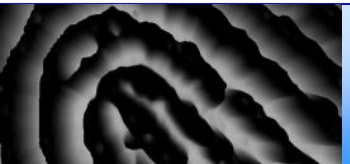
- The ridge-line flow can be effectively described by an orientation image
- The ridge line density can be summarized using a frequency image



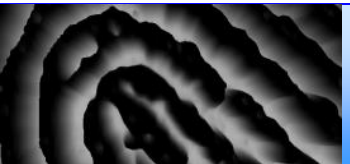
Fingerprint anatomy (3)

- At the very local level (e.g., acquisition at 1000 dpi) it is possible to identify sweat pores (from 60 to 250 μm), incipient ridges, creases, etc.

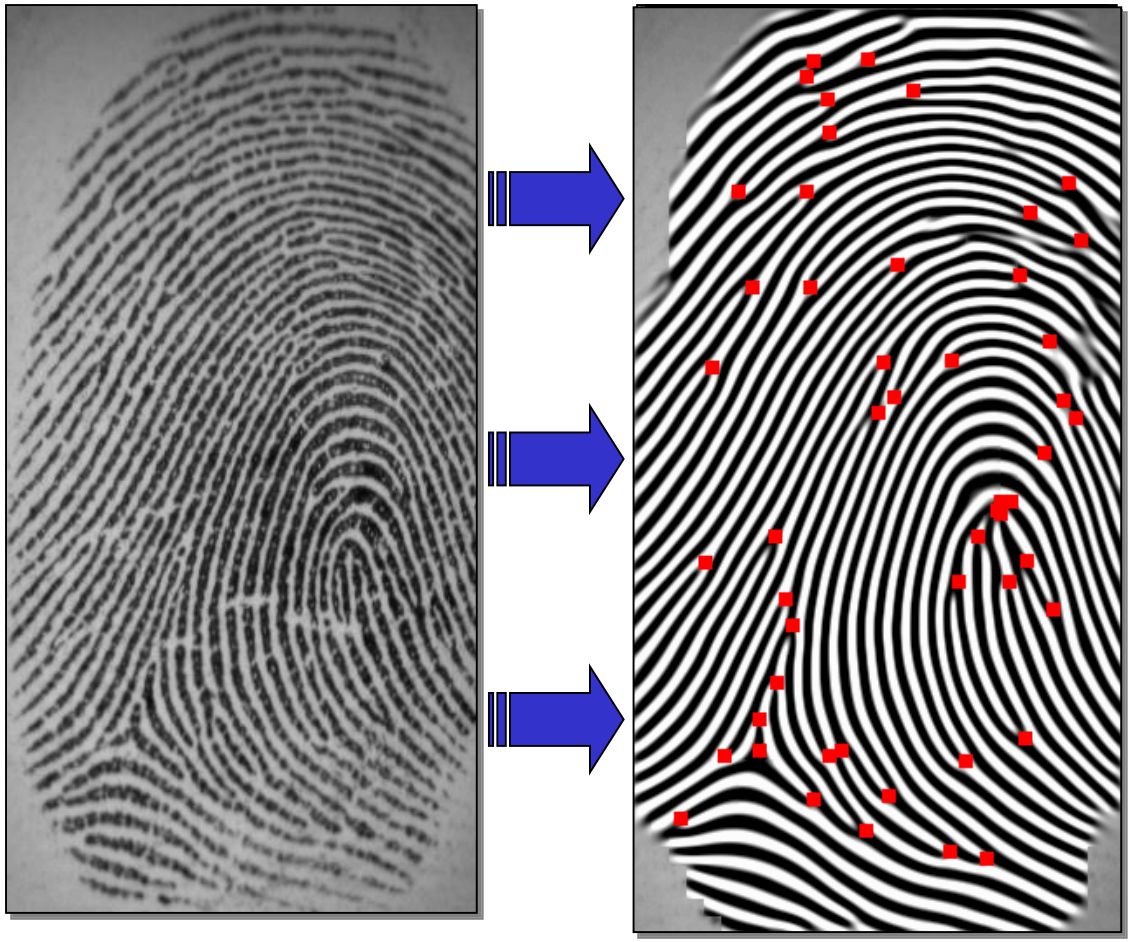


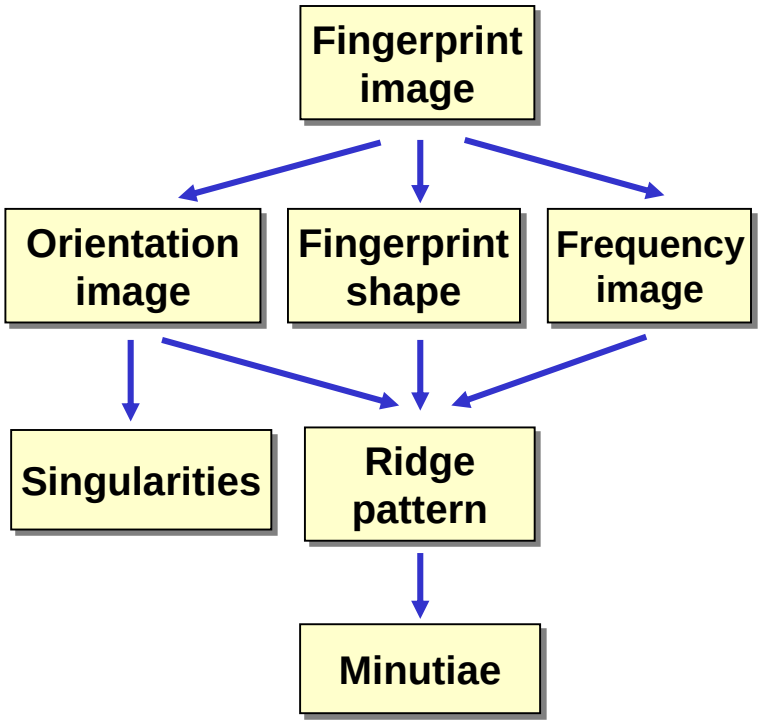


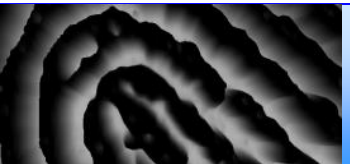
Fingerprint anatomy (4)



Feature extraction steps

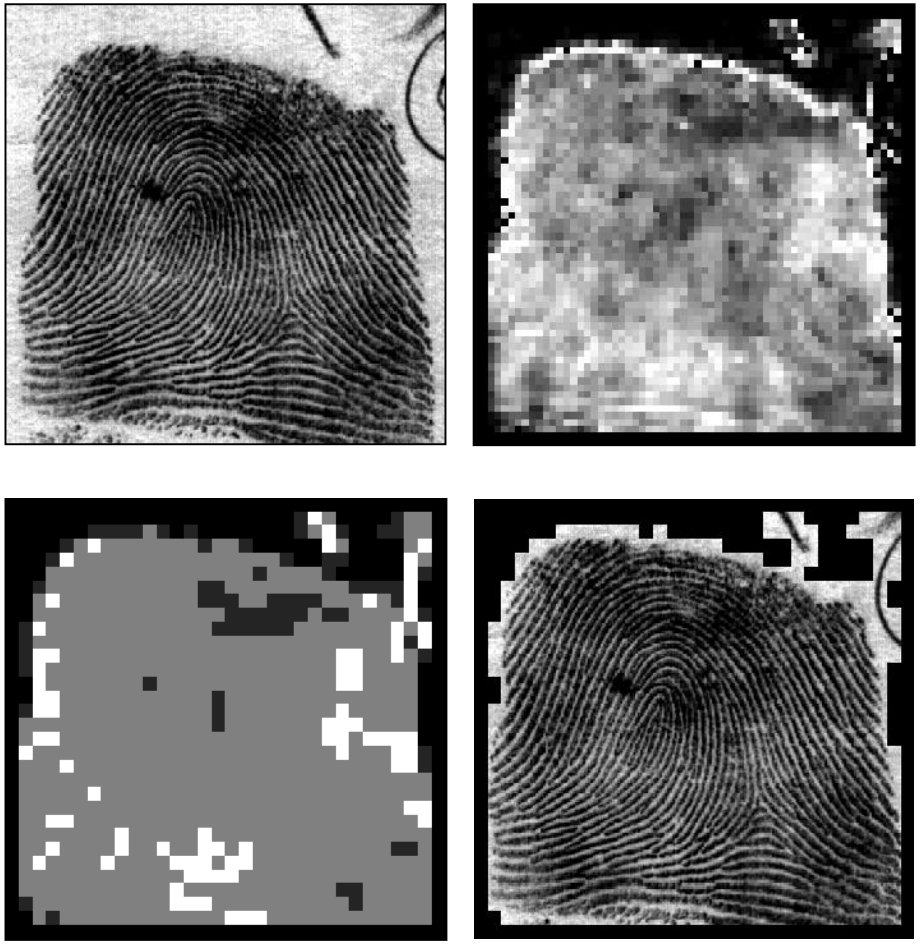


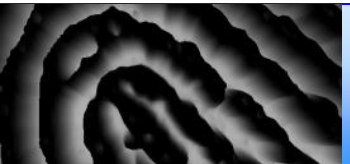




Segmentation

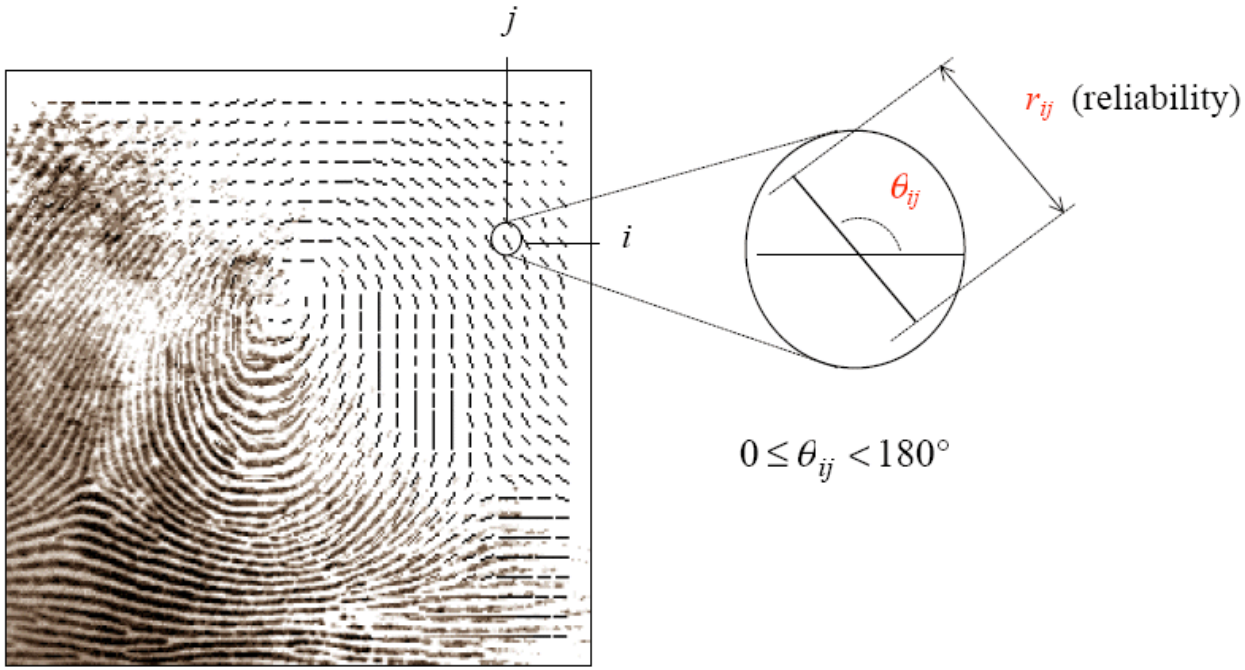
- The term *segmentation* is used to denote the separation of fingerprint area (foreground) from the image background.
- Foreground and background are discriminated by the presence of a striped and oriented pattern in the foreground and of an isotropic pattern in the background.
- How to measure anisotropy ?
  - presence of a well defined peak in a local histogram of orientations (Mehtre et al. (1987))
  - variance of the gray-levels in direction orthogonal to the gradient (Ratha, Chen, and Jain (1995))
  - magnitude of the gradient (Maio and Maltoni (1997))
  - combination of more features (Bazen and Gerez (2001b))



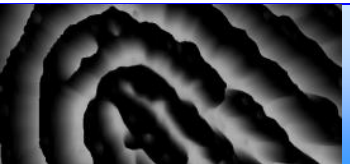


Local ridge orientation (1)

The local ridge orientation at [x,y] is the angle $\theta_{xy} \in [0..180°[$ that the fingerprint ridges, crossing through an arbitrary small neighborhood centered at [x,y], form with the horizontal axis.



The simplest and most natural approach for extracting local ridge orientation is based on computation of gradient phase angles (problems of non-linearity and circularity).



Local ridge orientation (2)

- Robust computation (based on local averaging of gradient estimates) as proposed by Kass and Witkin (1987), Bigun and Granlund (1987), G.:Donahue and Rokhlin (1993), Chen, and Jain (1995), and Bazen and Gerez (2002):

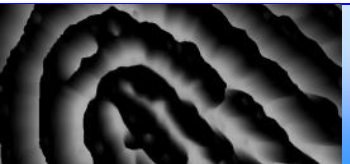
$$\theta_{ij} = 90^\circ + \frac{1}{2}\,\mathrm{atan2}\left(2G_{xy}, G_{xx} - G_{yy}\right),$$

$$G_{xy} = \sum_{h=-8}^{8}\sum_{k=-8}^{8} \nabla_x\left(x_i + h, y_j + k\right)\cdot \nabla_y\left(x_i + h, y_j + k\right),$$

$$G_{xx} = \sum_{h=-8}^{8}\sum_{k=-8}^{8} \nabla_x\left(x_i + h, y_j + k\right)^2,$$

$$G_{yy} = \sum_{h=-8}^{8}\sum_{k=-8}^{8} \nabla_y\left(x_i + h, y_j + k\right)^2,$$

where ∇x and ∇y are the x- and y-gradient components computed through 3×3 Sobel masks, and atan2(y,x) calculates the arctangent of the two variables y and x: it is similar to calculating the arctangent of y/x, except that the signs of both arguments are used to determine the quadrant of the result.



Smoothing local orientations

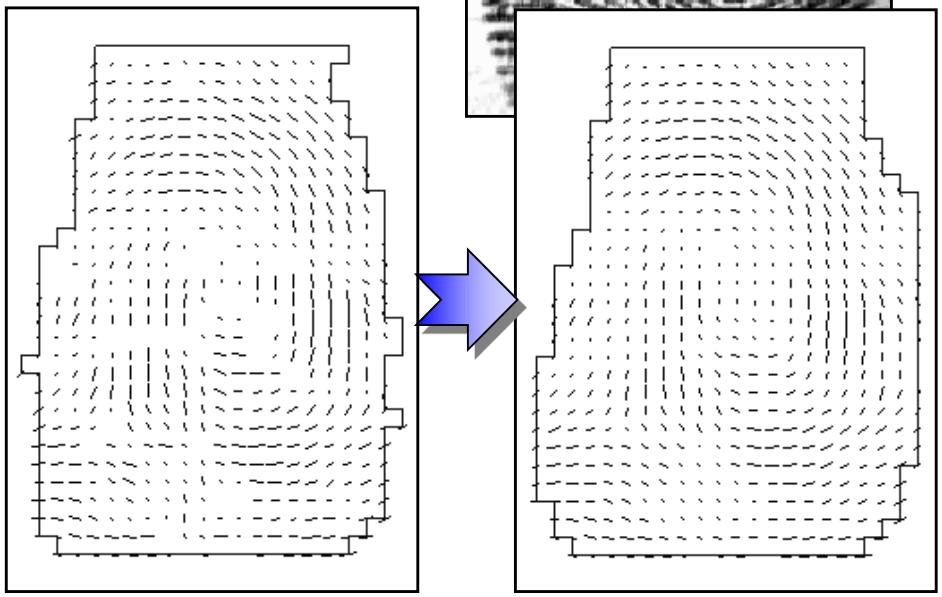
What is the average orientation between 5 and 175° ? and between 0 and 90° ?

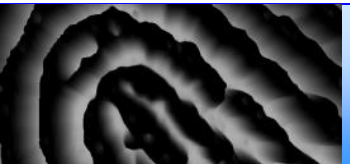
a simple but elegant solution is to double the angles; each element is encoded by the vector:

$$\mathbf{d}_{ij} = \left[r_{ij} \cdot \cos 2\theta_{ij}, r_{ij} \cdot \sin 2\theta_{ij} \right] ,$$

averaging the angles in a local $n \times n$ window, is performed by separately averaging the two (x and y) components:

$$\overline{\mathbf{d}} = \left[\frac{1}{n^2} \sum_{i,j} r_{ij} \cdot \cos 2\theta_{ij}, \frac{1}{n^2} \sum_{i,j} r_{ij} \cdot \sin 2\theta_{ij} \right]$$





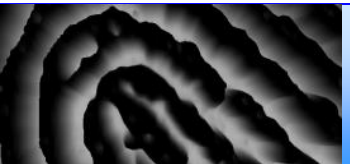
Orientation extraction algorithms

- **Local Analysis**: each orientation is estimated by using image information (pixels) from a local window.
  - Gradient
  - Slit-Based (Slit [Oliveira07])
  - Frequency Domain (STFT [Govindaraju07])
  - Tracing Based (Line-sensor [Gottschlich09])

- **Global Analysis**: each orientation is estimated according to a global model.
  - Geometric Models (need singular points)
  - Global Approximation (FOMFE [Wang07], Legendre Polynomials [Ram10])

- **Learning-based**: each orientation is estimated according to a global model.
  - Dictionaries (AFROM [Ram09], Dictionary of patches [Feng13][Yang14][Cao14][Cao16])
  - Convolutional Neural Networks ([Cao15][Schuch17])

F. Turroni, D. Maltoni, R. Cappelli and D. Maio, "Improving Fingerprint Orientation Extraction", IEEE Transactions on Information Forensics and Security, vol.6, no.3, pp.1002-1013, September 2011.

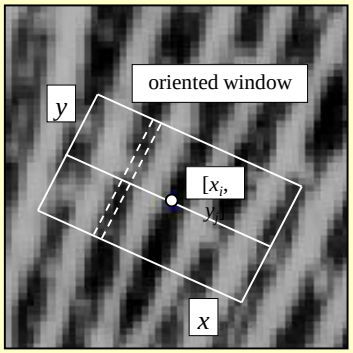


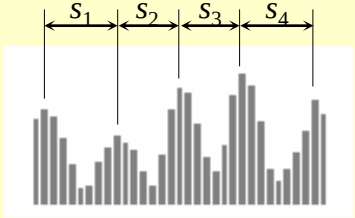
Local ridge frequency (1)

- The local ridge frequency (or density) f_{xy} at point $[x,y]$ is the number of ridges per unit length along a hypothetical segment centered at $[x,y]$ and orthogonal to the local ridge orientation θ_{xy}.

- Counting-based approach (Hong, Wan, and Jain (1998)):
- Variation-based approach (Maio and Maltoni (1998a))
- Estimation in the Fourier domain (Kovacs, Rovatti, and Frazzoni (2000)):

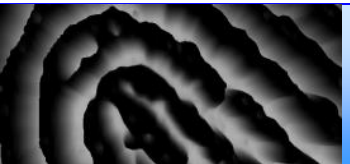
Counting-based approach





x-signature

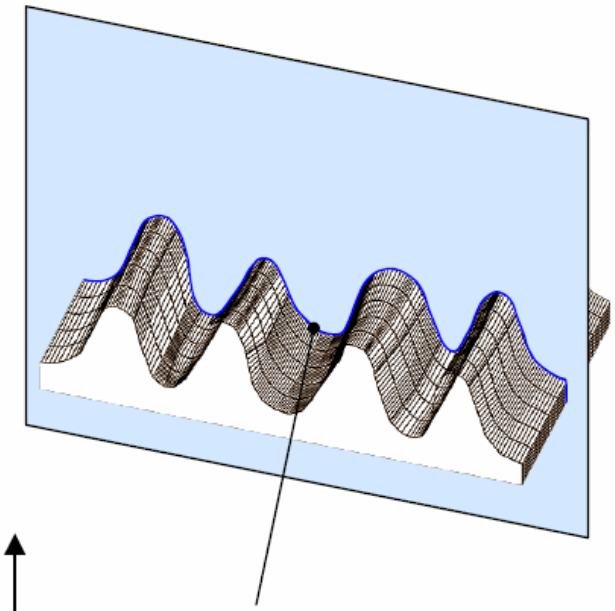
$$f_{ij} = \frac{4}{s_1 + s_2 + s_3 + s_4}$$



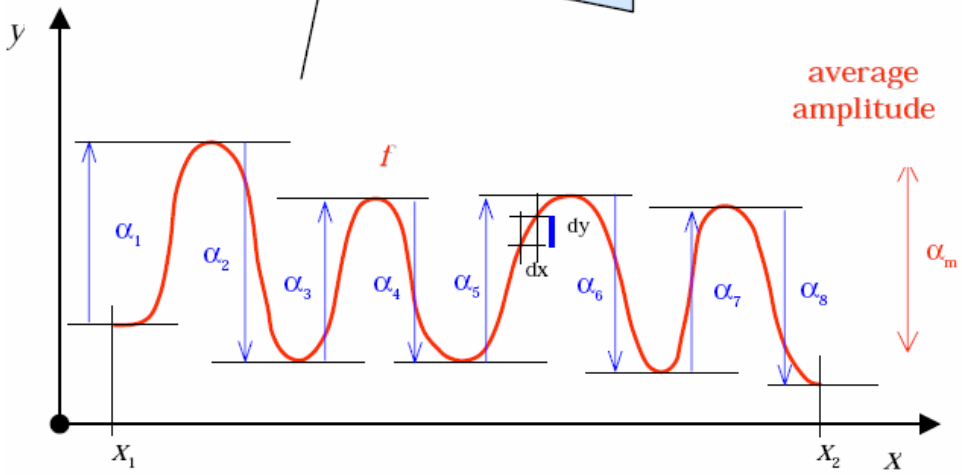
Local ridge frequency (2)

Variation-based approach

Maio and Maltoni (1998a)



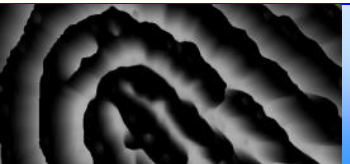
the ridge-line local density corresponds to the frequency ν of f, that is the number of periods per unit length



Variation of f

$$V(f) = \int_{x_1}^{x_2} \left| \frac{df(x)}{dx} \right| \cdot dx = \int_{x_1}^{x_2} \left| \frac{dy}{dx} \cdot dx \right| = \alpha_1 + \alpha_2 + \ldots \alpha_8$$

$$V(f) = (x_2 - x_1) \cdot 2\nu \cdot \alpha_m \quad \Rightarrow \quad \nu = \frac{V(f)}{2(x_2 - x_1) \cdot \alpha_m}$$



Fingerprint quality: NFIQ

- NIST Fingerprint Image Quality (**NFIQ**) is the *de facto standard* to quantify fingerprint quality (open source)
- NFIQ (1.0) assigns to a fingerprint a value in {1,2,3,4,5} which is in inverse proportion with its quality
- NFIQ is an **operational quality** aimed at predicting fingerprint recognition accuracy:
  - 1 → top quality, small errors
  - 5 → very low quality, high errors

{1,2,3,4,5}

Fingerprint quality: NFIQ 2.0

- Released April 2016 (open source)
- NFIQ 2.0 quality value is in [0..100]
  - 0 no utility
  - 100 highest utility value
- Quality features
  - 155 evaluated
  - 14 selected (es. orientation certainty, ridge valley uniformity, …)

[0..100]

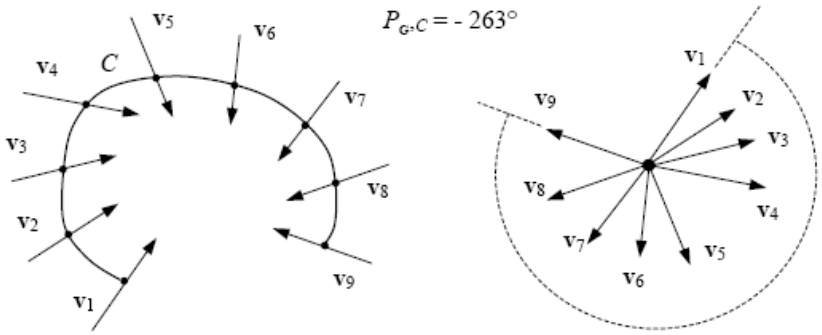
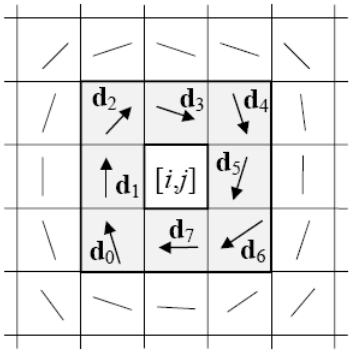
Singularity detection (1)

The best-known method is based on Poincaré index (Kawagoe and Tojo (1984)).

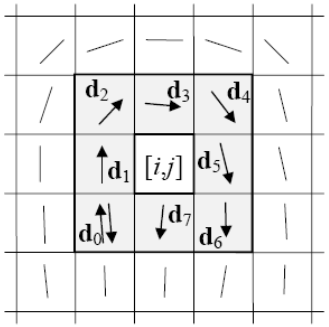


The Poincaré index $P_{G,C}(i,j)$ at $[i,j]$ is computed as:

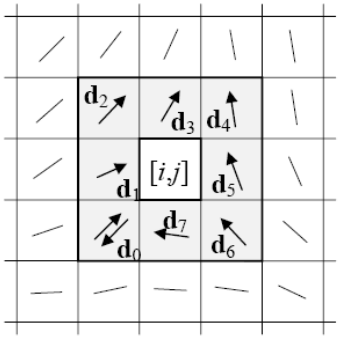
- The (closed) curve C is an ordered sequence of orientations, such that $[i,j]$ is an internal point
- $P_{G,C}(i,j)$ is computed by algebraically summing the orientation differences between adjacent elements of C. Summing orientation differences requires a direction (among the two possible) to be associated at each orientation. *A solution to this problem is to randomly select the direction of the first element and assign the direction closest to that of the previous element to each successive element.*



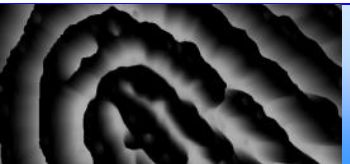
$P_{G,C}(i,j) = 360°$
whorl



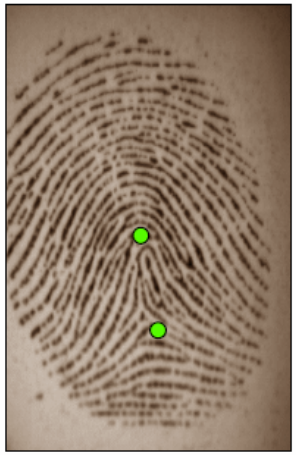
$P_{G,C}(i,j) = 180°$
loop

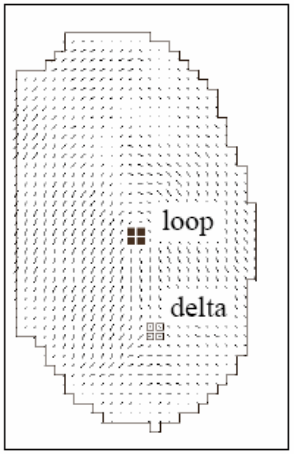


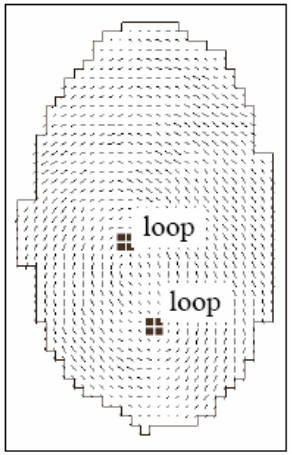
$P_{G,C}(i,j) = -180°$
delta



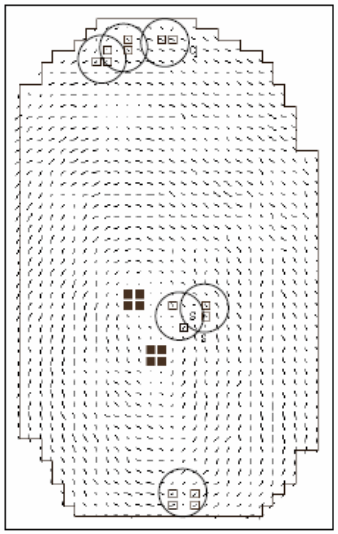
Singularity detection (2)

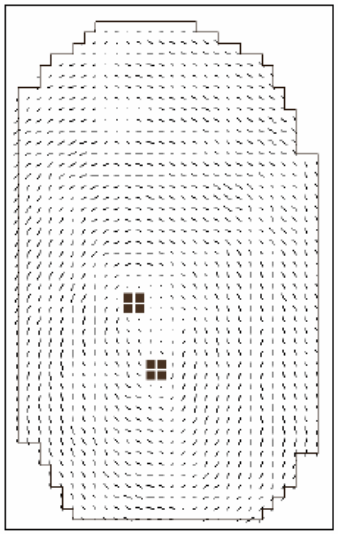






Smoothing of local orientation is necessary to control noise.



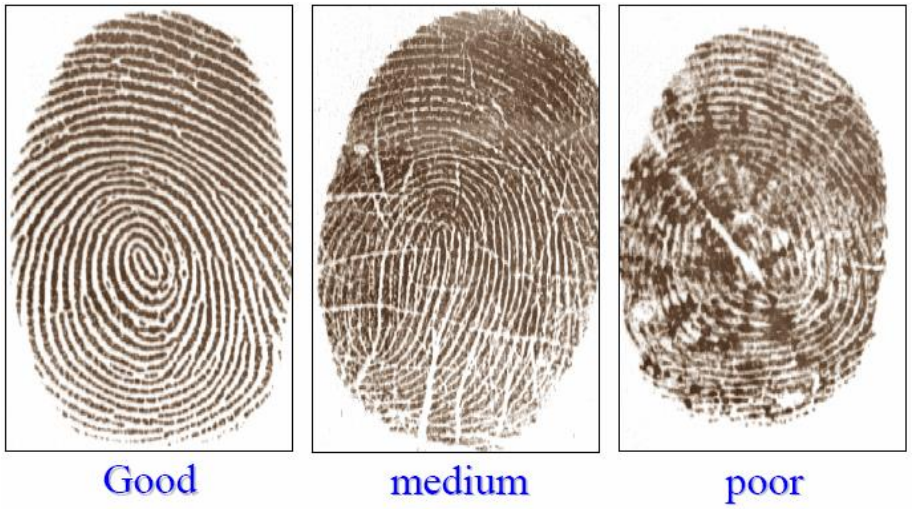


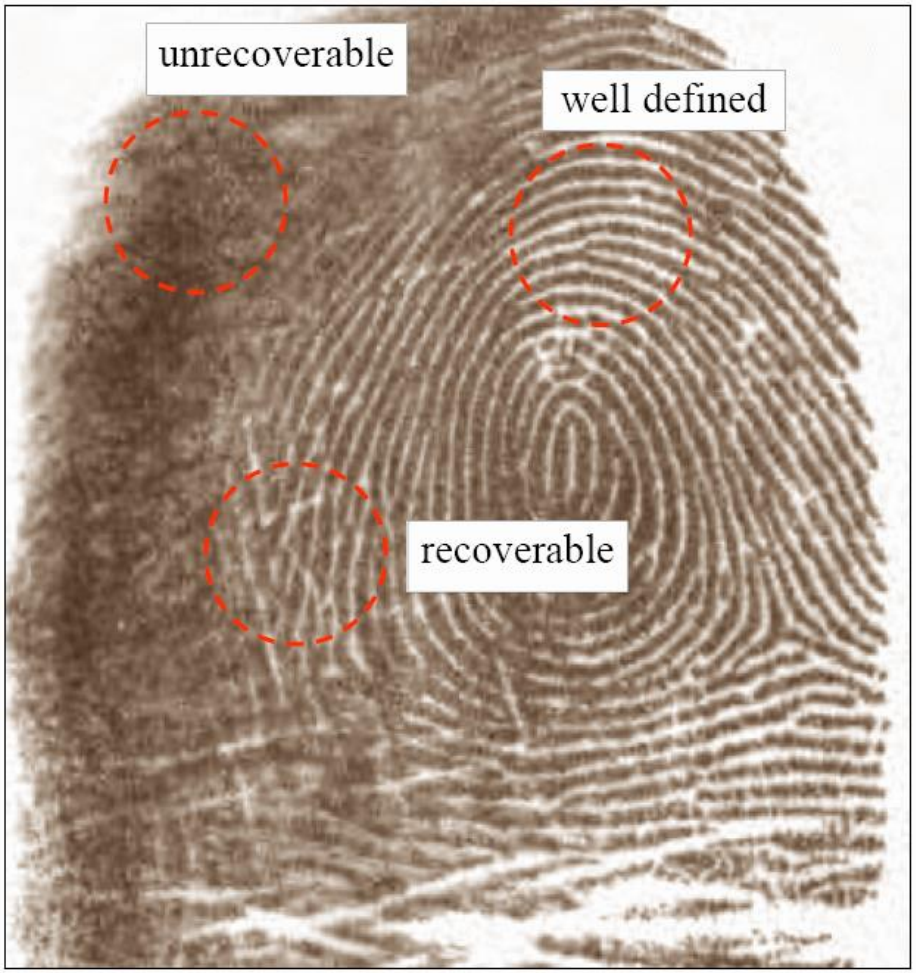
How much smoothing ?

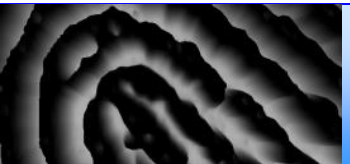
➔Iteratively smooth until a valid number of singularities is detected **Karu and Jain (1996)**

Enhancement (1)

- Aimed at **improving the quality** of **recoverable regions** to simplify successive stages

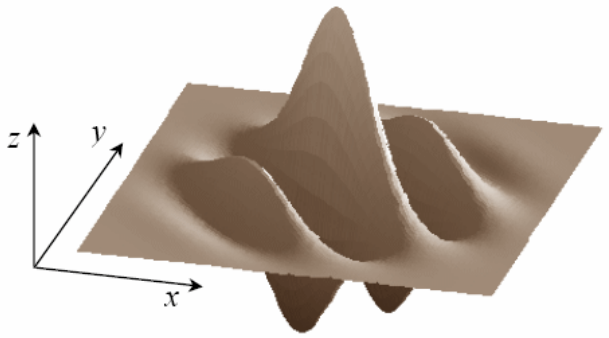


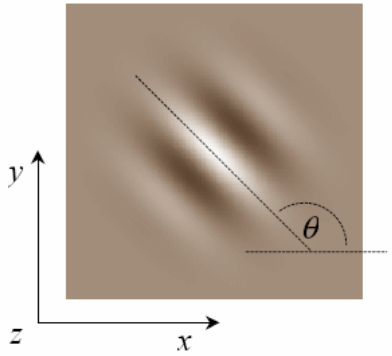




Enhancement (2)

Best results with contextual filters (e.g. Gabor filters).

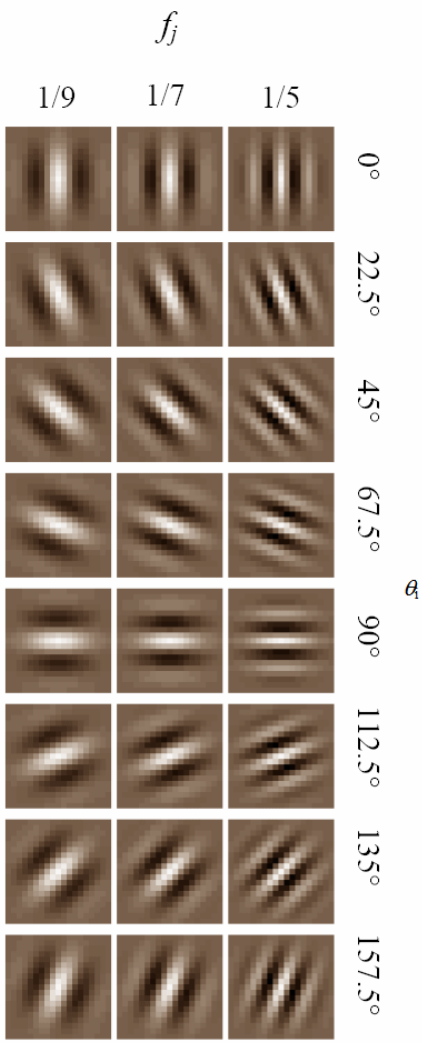


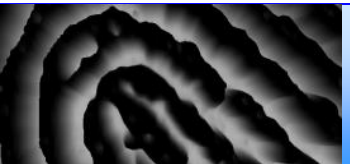


$$g(x,y:\theta,f)=\exp\left\{-\frac{1}{2}\left[\frac{x_\theta^{\,2}}{\sigma_x^{\,2}}+\frac{y_\theta^{\,2}}{\sigma_y^{\,2}}\right]\right\}\cdot\cos(2\pi f\cdot x_\theta),$$

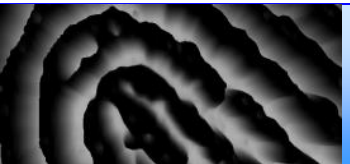
$$\begin{bmatrix}x_\theta\\ y_\theta\end{bmatrix}=\begin{bmatrix}\cos(90^\circ-\theta) & \sin(90^\circ-\theta)\\ -\sin(90^\circ-\theta) & \cos(90^\circ-\theta)\end{bmatrix}\begin{bmatrix}x\\ y\end{bmatrix}=\begin{bmatrix}\sin\theta & \cos\theta\\ -\cos\theta & \sin\theta\end{bmatrix}\begin{bmatrix}x\\ y\end{bmatrix}$$

Each pixel $[x,y]$ of the image is convolved with the filter $g_{ij}(x,y)$ such that θ_i is the discretized orientation closest to θ_{xy} and f_j is the discretized frequency closest to f_{xy}.





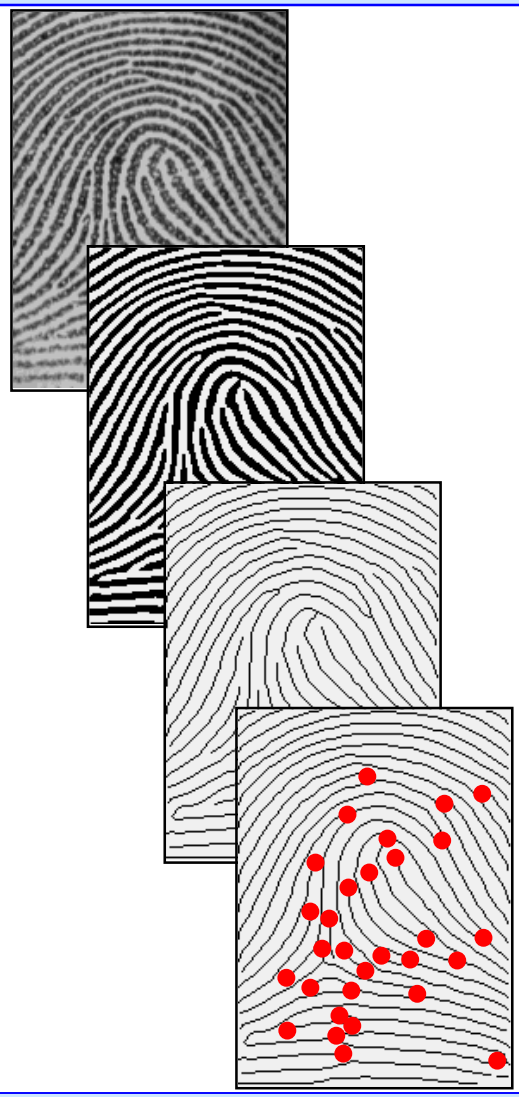
Enhancement (3)

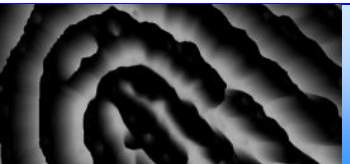


Automatic minutiae detection

- An extremely important task: a lot of research has been devoted to this topic.

- Traditional approach:
  1. **Binarization**: the fingerprint gray-scale image is converted into a binary image
  2. **Thinning**: the binary image is submitted to a thinning stage (the ridge-line thickness is reduced to one pixel)
  3. **Detection**: a simple image scan allows to detect the pixels that correspond to minutiae

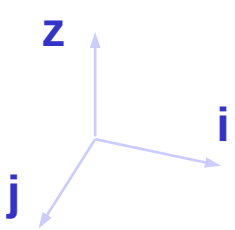


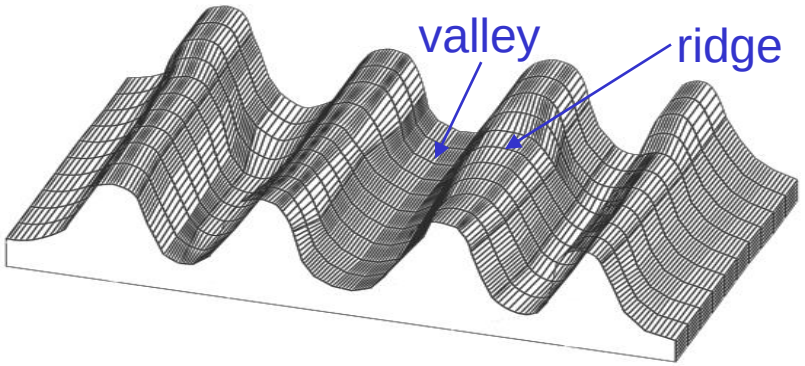


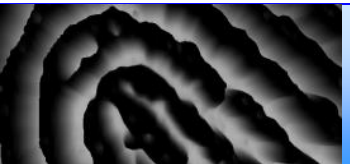
Direct gray-scale minutiae detection (1)

- Problems of the binarization-based approaches:
  - a **significant amount of information** may be **lost** during the binarization process
  - binarization and thinning are **time-consuming**
  - thinning may introduce a large number of **spurious minutiae**
  - most of the binarization techniques proved to be unsatisfactory when applied to low-quality images

Follow the ridge lines on the gray-scale image, by “sailing” according to the local orientation of the ridge pattern

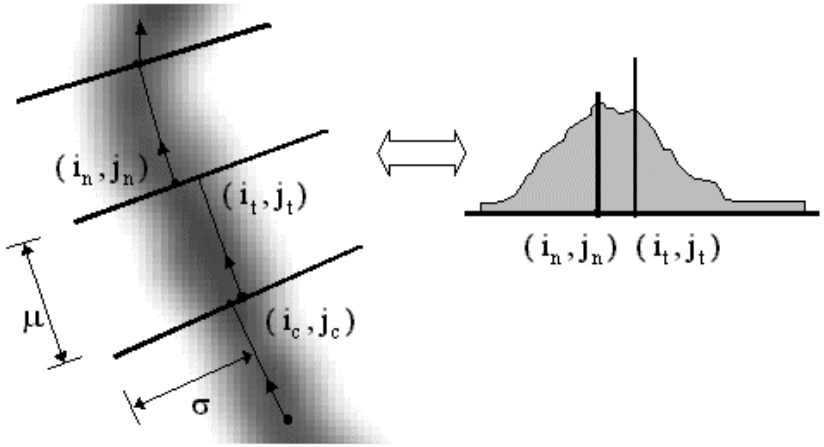




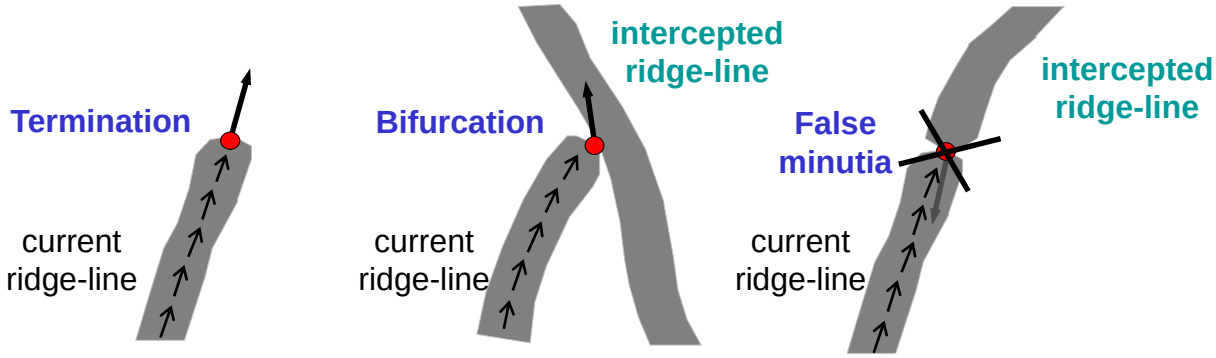


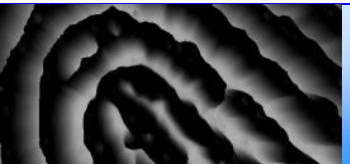
Direct gray-scale minutiae detection (2)

A ridge-line is made of a set of points that are the local maxima with respect to the direction orthogonal to the ridge-line itself

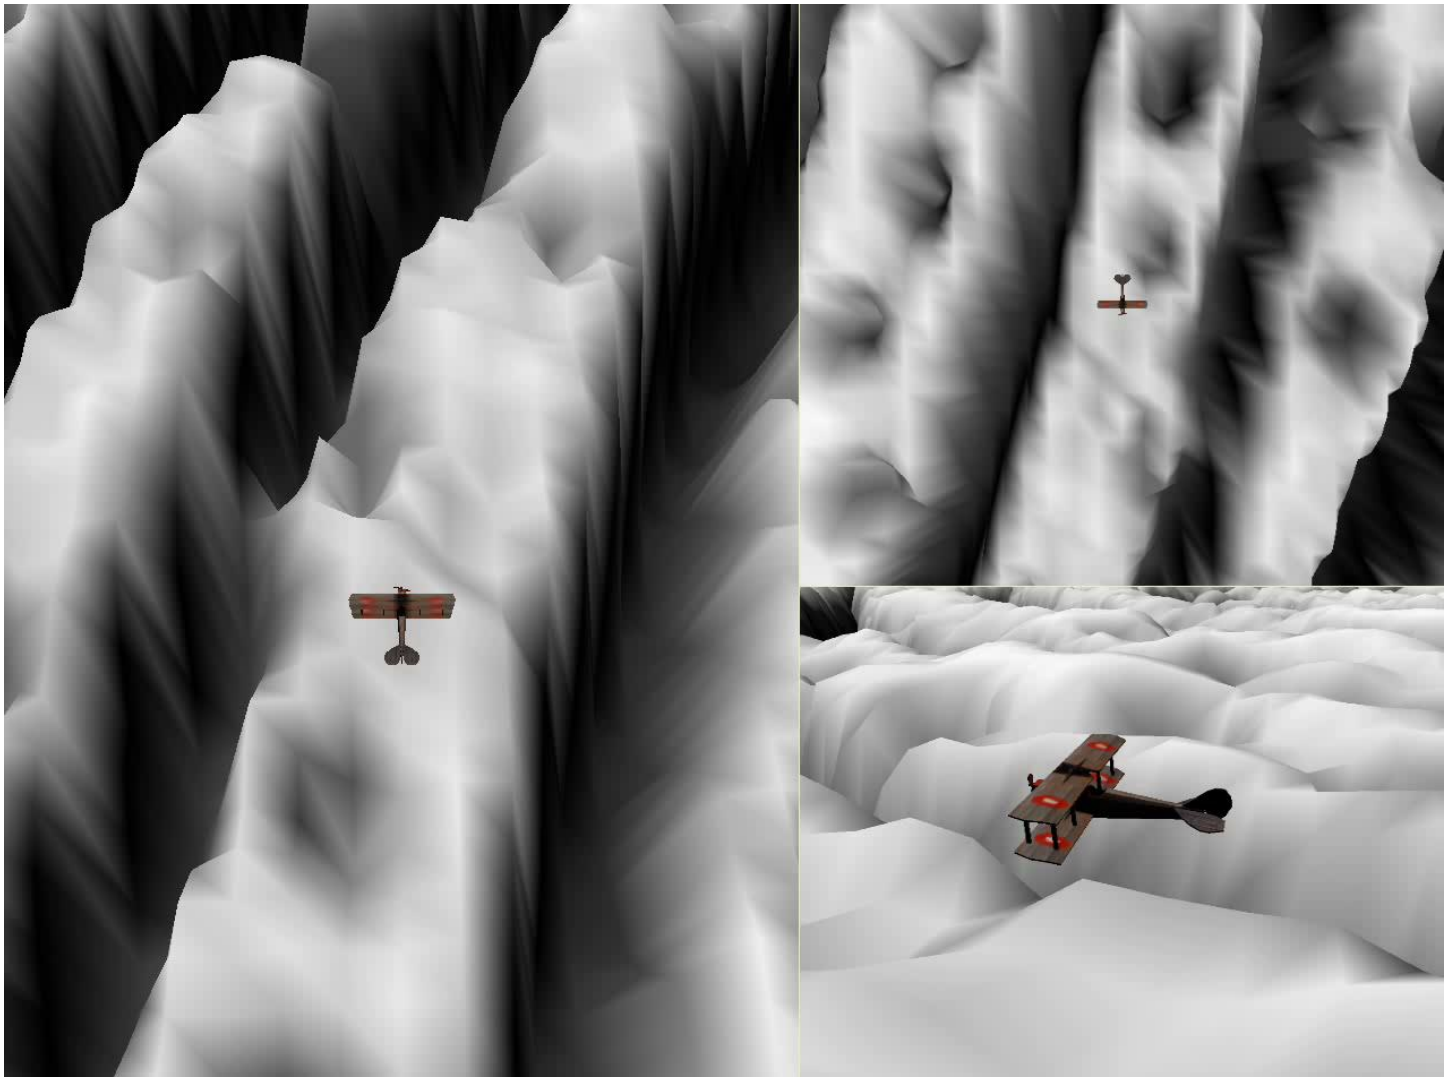


A set of starting points is determined (according to a square-mesh grid superimposed to the image); for each point, the algorithm find the nearest ridge-line and follows it until a bifurcation or a termination is reached.



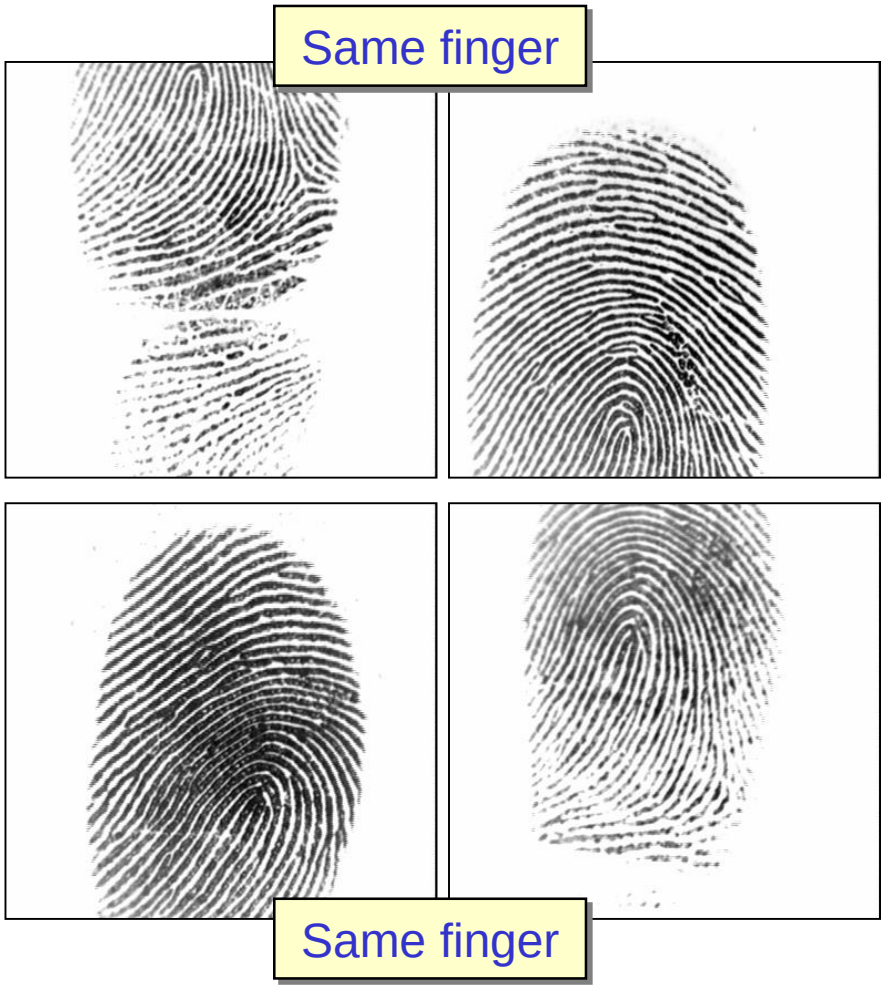


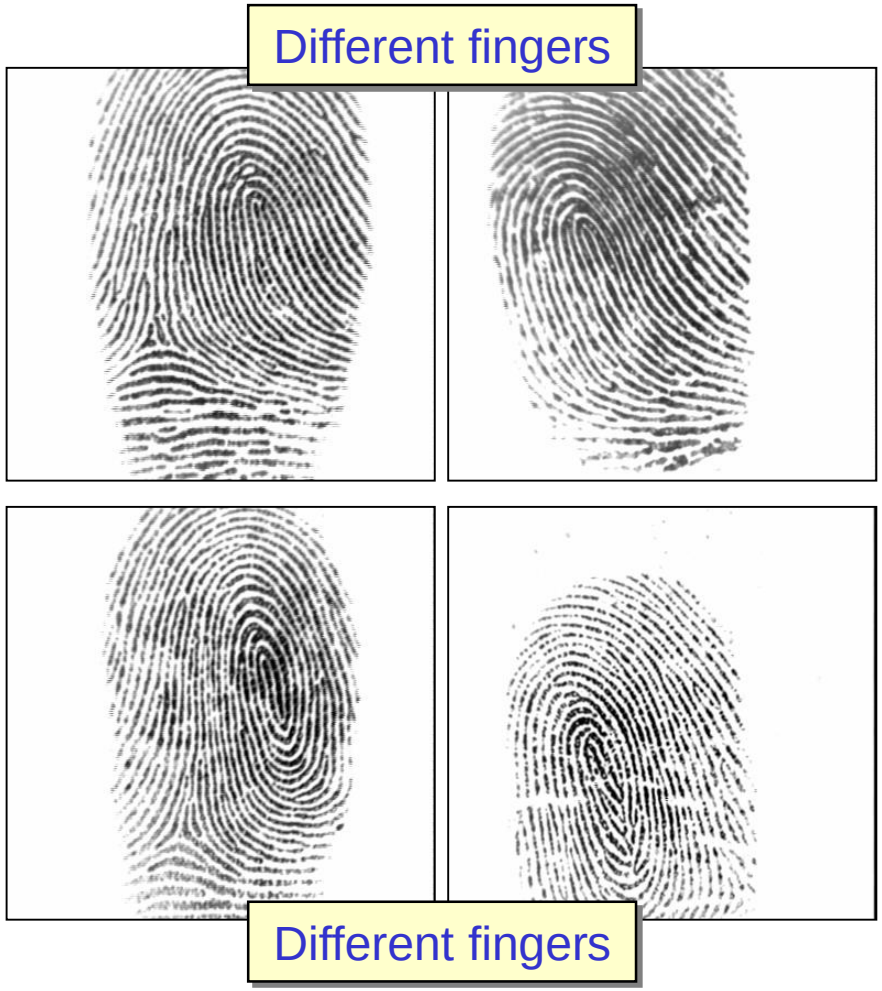
Direct gray-scale minutiae detection - Demo

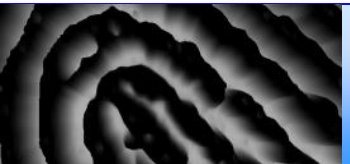


Fingerprint recognition

- Finding the similarity between two fingerprints

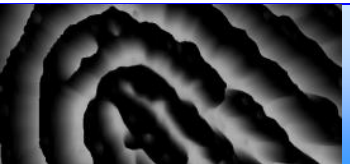




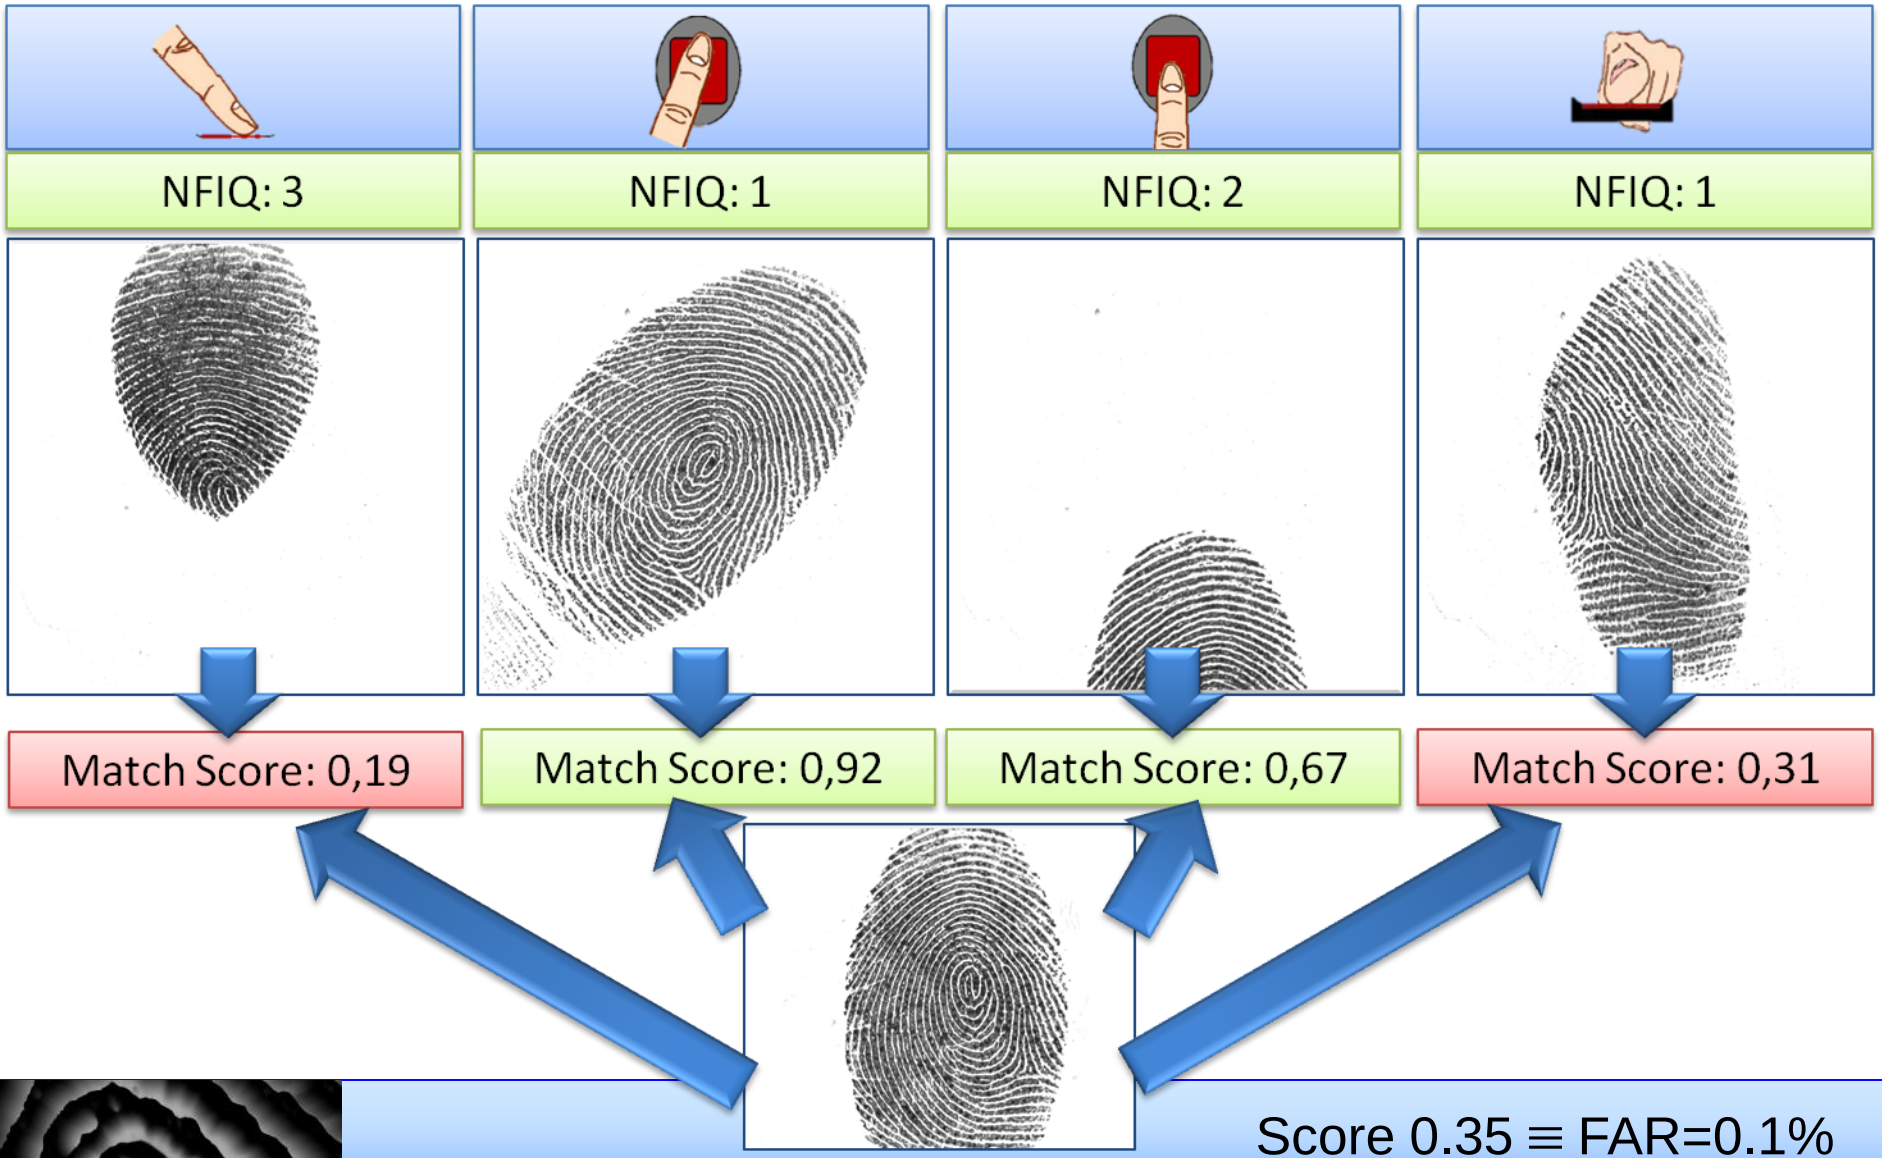


Fingerprint recognition: main challenges

- High displacement and/or rotation
  - Small overlap between the template and the input fingerprints. This problem is particularly serious for *small-area sensors*. A finger displacement of just 2 mm (imperceptible to the user) results in a translation of about 40 pixels in a fingerprint image scanned at 500 dpi.
- Non-linear distortion
  - The act of sensing maps the three-dimensional shape of a finger onto the two-dimensional surface of the sensor. This results in a non-linear distortion in successive acquisitions of the same finger due to skin plasticity.
- Different pressure and skin condition
  - Non uniform finger pressure, dryness of the skin, skin disease, sweat, dirt, grease, and humidity in the air.
- Feature extraction errors
  - Feature extraction algorithms are imperfect and often introduce measurement errors, in particular in *low-quality fingerprint images*



Bad positioning



Score 0.35 ≡ FAR=0.1%

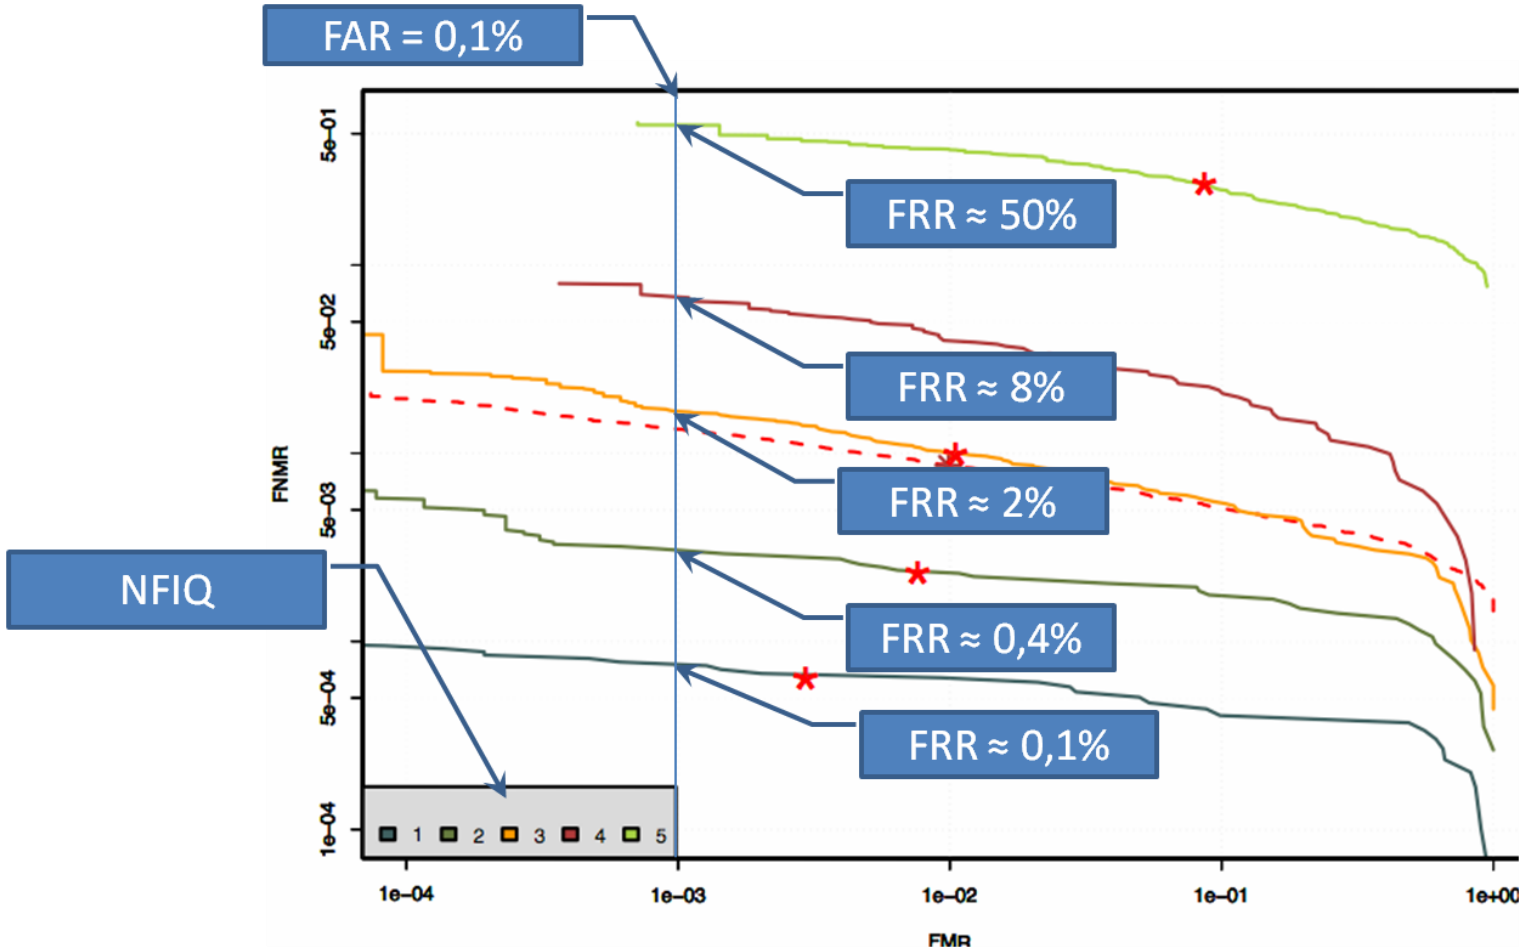
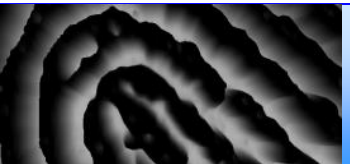
NFIQ = 5 examples

Quality/Accuracy tradeoff

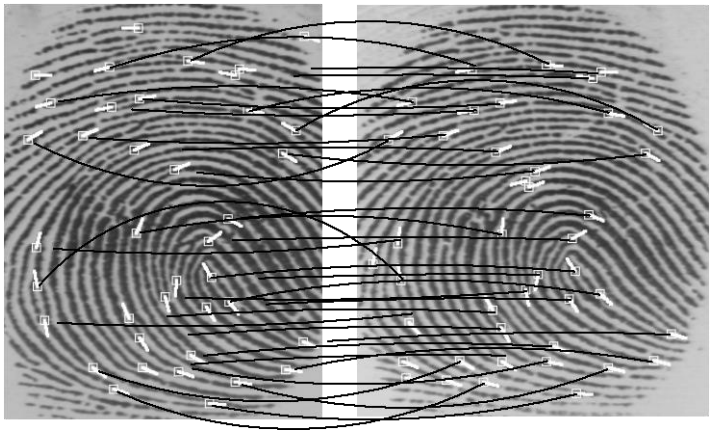


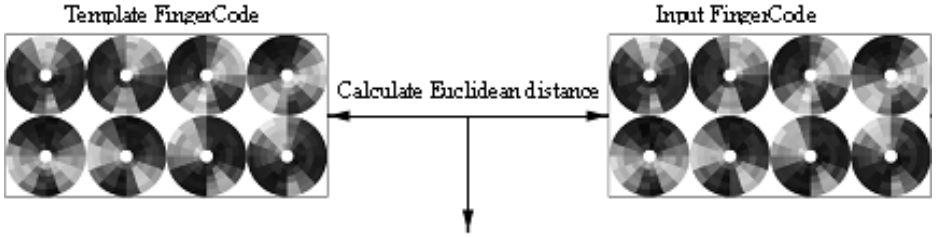
Tabassi E., “The Last 1% - Biometric Quality Assessment for Error Suppression”, Biometric Consortium Conference, 2007.

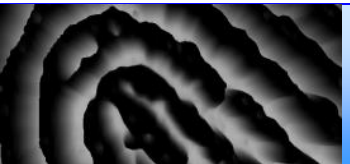


Fingerprint matching approaches (1)

- Minutiae-based matching
  - The most popular and widely used technique. Minutiae-based matching consists in finding the alignment that results in the maximum number of minutiae pairings.
- Correlation-based matching
  - Two fingerprints are superimposed and the correlation between corresponding pixels is computed for different alignments.
- Ridge feature-based matching
  - Other features of the fingerprint ridge pattern (e.g., *local orientation* and *frequency*, *ridge shape*, *texture information*) may be extracted more reliably than minutiae in *low-quality images*.

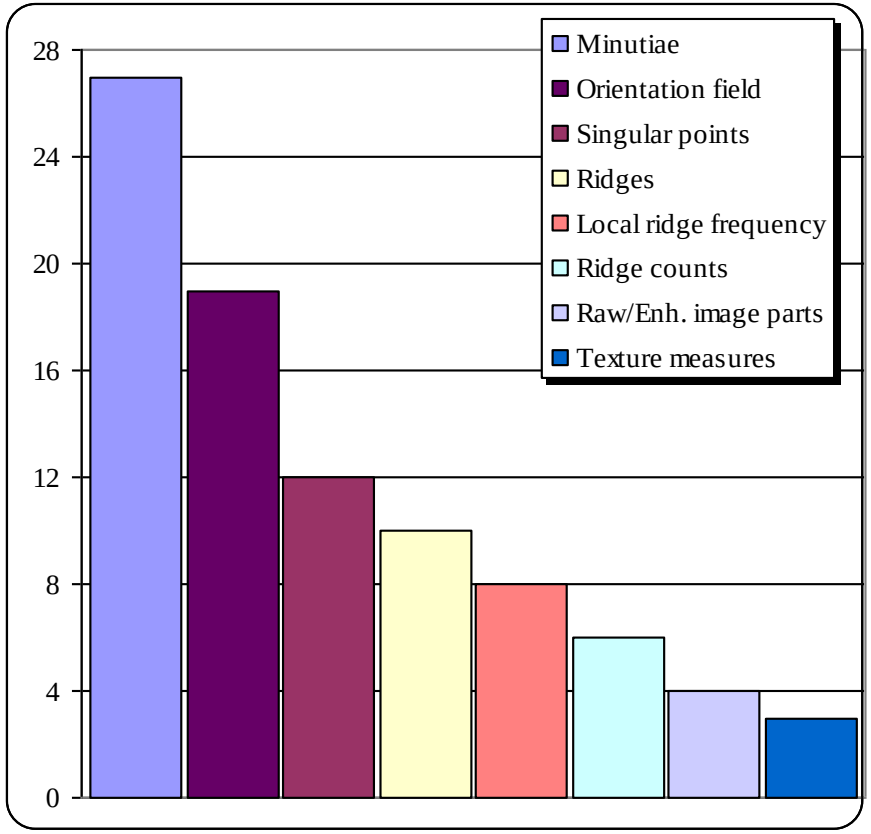




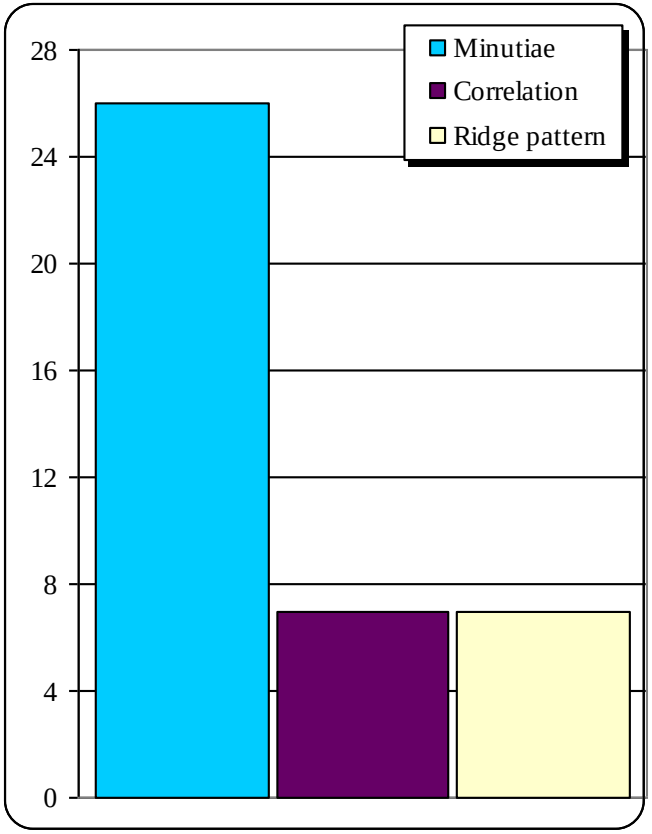


Fingerprint matching approaches (2)

State of the art algorithms: features extracted and matching approaches adopted (source: 29 algorithms from FVC2004)



Features extracted



Matching approaches

Minutiae-based matching: Problem formulation

$$\mathbf{T} = \{\mathbf{m}_1, \mathbf{m}_2, ..., \mathbf{m}_m\} \quad \mathbf{m}_i = \{x_i, y_i, \theta_i\} \quad i = 1..m$$
$$\mathbf{I} = \{\mathbf{m}'_1, \mathbf{m}'_2, ..., \mathbf{m}'_n\} \quad \mathbf{m}'_j = \{x'_j, y'_j, \theta'_j\} \quad j = 1..n,$$

the two sets of minutiae corresponding to the Template and the Input

$$\underset{\Delta x, \Delta y, \theta, P}{\text{maximize}} \sum_{i=1}^{m} mm\left(map_{\Delta x, \Delta y, \theta}\left(\mathbf{m}'_{P(i)}\right), \mathbf{m}_i\right)$$

maximize the number of minutiae mates between template and "aligned" Input

$P(i)$ is an unknown function that determines the pairing between **I** and **T** minutiae:

1. $P(i) = j$ indicates that the mate of the $\mathbf{m}_i$ in **T** is the minutia $\mathbf{m}'_j$ in **I**;
2. $P(i) =$ null indicates that minutia $\mathbf{m}_i$ in **T** has no mate in **I**;
3. a minutia $\mathbf{m}'_j$ in **I**, such that $\forall\, i = 1..m$, $P(i) \neq j$ has no mate in **T**;
4. $i = 1..m$, $k = 1..m$, $i \neq k \Rightarrow P(i) \neq P(k)$ or $P(i) = P(k) =$ null (each minutia in **I** is associated with a maximum of one minutia in **T**).

$$mm\left(\mathbf{m}''_j, \mathbf{m}_i\right) = \begin{cases} 1 & sd\left(\mathbf{m}''_j, \mathbf{m}_i\right) \leq r_0 \quad \text{and} \quad dd\left(\mathbf{m}''_j, \mathbf{m}_i\right) \leq \theta_0 \\ 0 & \text{otherwise.} \end{cases}$$

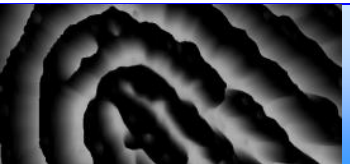
$$dd\left(\mathbf{m}'_j, \mathbf{m}_i\right) = \min\left(\left|\theta'_j - \theta_i\right|, 360^\circ - \left|\theta'_j - \theta_i\right|\right)$$

$$sd\left(\mathbf{m}'_j, \mathbf{m}_i\right) = \sqrt{\left(x'_j - x_i\right)^2 + \left(y'_j - y_i\right)^2}$$

the two minutiae can be paired

$$map_{\Delta x, \Delta y, \theta}\left(\mathbf{m}'_j = \{x'_j, y'_j, \theta'_j\}\right) = \mathbf{m}''_j = \{x''_j, y''_j, \theta'_j + \theta\}$$

$$\begin{bmatrix} x''_j \\ y''_j \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x'_j \\ y'_j \end{bmatrix} + \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}$$



Global minutiae matching (1)

... an Hough transform-based approach (Ratha et al. (1996))

The space of transformations consists of quadruples (Δx, Δy, θ, s), where each parameter is discretized (denoted by the symbol $^+$) into a finite set of values:

$$\Delta x^+ \in \{\Delta x_1^+, \Delta x_2^+, ..., \Delta x_a^+\} \quad \Delta y^+ \in \{\Delta y_1^+, \Delta y_2^+, ..., \Delta y_b^+\},$$
$$\theta^+ \in \{\theta_1^+, \theta_2^+, ..., \theta_c^+\} \quad s^+ \in \{s_1^+, s_2^+, ..., s_d^+\}.$$

At the end of the accumulation process, the best alignment transformation (Δx^*, Δy^*, θ^*, s^*) is then obtained as

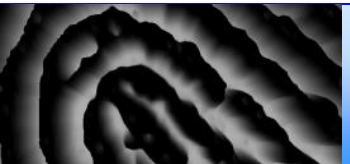
$$(\Delta x^*, \Delta y^*, \theta^*, s^*) = arg \max_{\Delta x^+, \Delta y^+, \theta^+, s^+} \mathbf{A}[\Delta x^+, \Delta y^+, \theta^+, s^+]$$

Computational complexity: $O(m \times n \times c \times d)$

for each $\mathbf{m}_i$, $i = 1..m$
  for each $\mathbf{m}'_j$, $j = 1..n$
    for each $\theta^+ \in \{\theta_1^+, \theta_2^+, ..., \theta_c^+\}$
      if $dd(\theta'_j + \theta^+, \theta_i) < \theta_0$
        for each $s^+ \in \{s_1^+, s_2^+, ..., s_d^+\}$

$$\{ \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} = \begin{bmatrix} x_i \\ y_i \end{bmatrix} - s^+ \cdot \begin{bmatrix} \cos\theta^+ & -\sin\theta^+ \\ \sin\theta^+ & \cos\theta^+ \end{bmatrix} \begin{bmatrix} x'_j \\ y'_j \end{bmatrix}$$

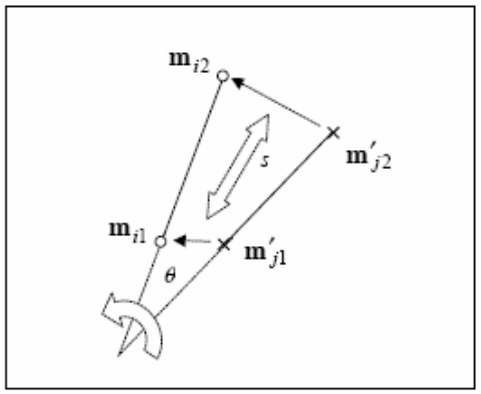
$\Delta x^+, \Delta y^+$ = quantization of Δx, Δy to the nearest bin
$\mathbf{A}[\Delta x^+, \Delta y^+, \theta^+, s^+] = \mathbf{A}[\Delta x^+, \Delta y^+, \theta^+, s^+] + 1$
}



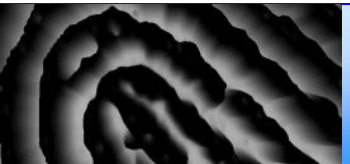
Global minutiae matching (2)

Several variants of the above algorithm:

- scale is often fixed to 1 (3-dimensional search space instead of 4-dimensional search space)
- considering two pairs of minutiae, rotation and scale parameters can be derived independently of the translation (Chang et al. (1997)) ...



from the pairing of two minutiae in I with two minutiae in T it is possible to derive scale and rotation...



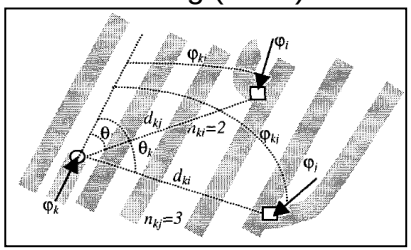
Local minutiae matching

Local minutiae matching *consists of comparing two fingerprints according to local minutiae structures.*

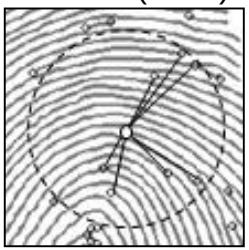
Local structures *are characterized by attributes that are invariant with respect to global transformations (e.g., translation, rotation, etc.) and therefore are suitable for matching without any a priori global alignment.*

Matching local minutiae structures *is usually* ***faster*** *and* ***more robust*** *to distortion, but* ***less distinctive****.*

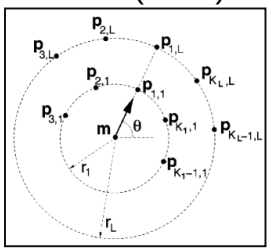
Jiang (2000)



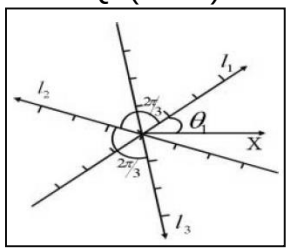
Ratha (2000)



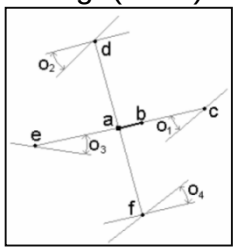
Tico (2003)



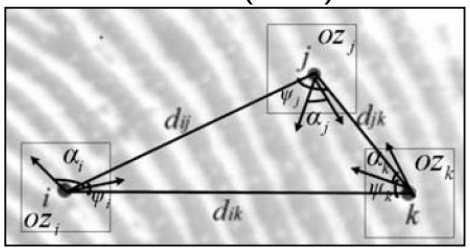
Qi (2004)



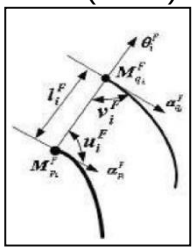
Ng (2004)



Chen (2005)



He (2006)



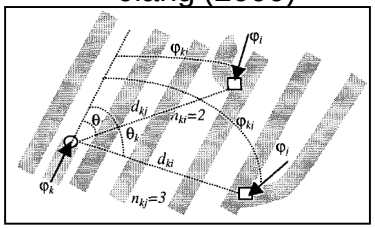
Feng (2008)

Families of local structures

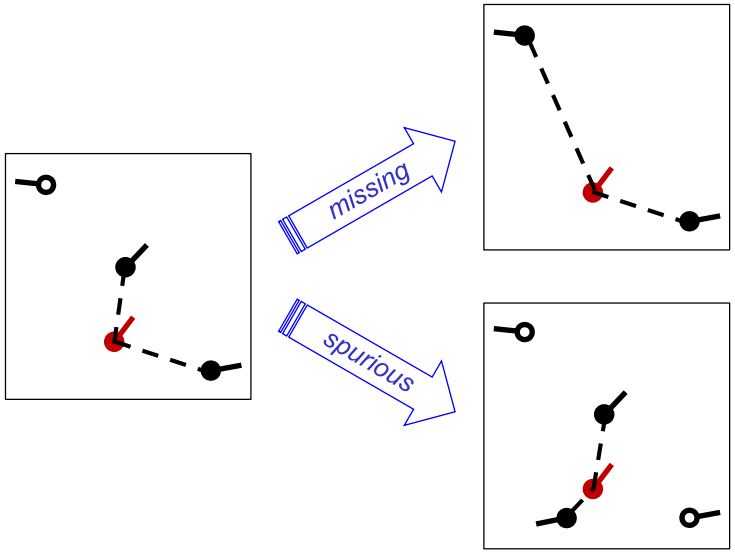
Nearest neighbour-based structures:

the neighbors of the central minutia are formed by its *K* spatially closest minutiae. This leads to *fixed-length descriptors* that can be usually matched very efficiently.

Jiang (2000)



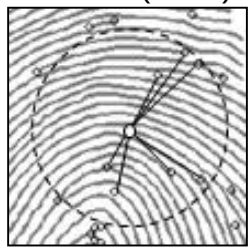
Drawback: the possibility of exchanging nearest neighbour minutiae due to missing or spurious ones.



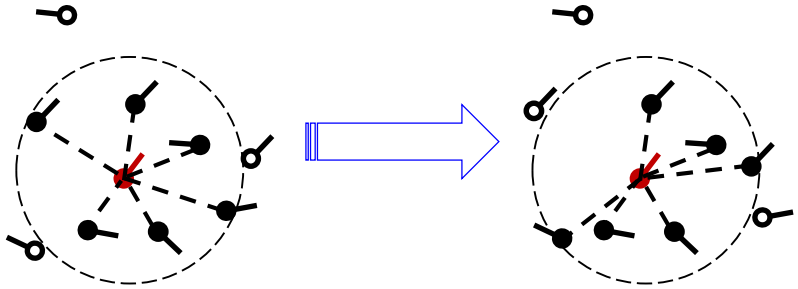
Fixed radius-based structures:

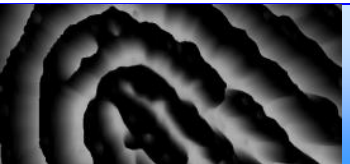
the neighbors are defined as all the minutiae that are closer than a given radius R from the central minutia. The *descriptor length is variable* and depends on the local minutiae density; this can lead to a more complex local matching; however, in principle, missing and spurious minutiae can be better tolerated.

Ratha (2000)



Drawback: border errors. Minutiae close to the local region border in one of the two fingerprints can be mismatched because of different local distortion or location inaccuracy that cause the same minutiae to move out of the local region in the second fingerprint.





MCC: Minutiae Cylinder Code

- Fixed radius structure;
- Fixed-length descriptors;
- Fast and simple matching phase;
- Matching algorithm compliant to ISO/IEC 19794-2 (2005);
- Portable on inexpensive secure platforms.

The similarity between two cylinders:

$$\mathbf{c}_m[lin(i,j,k)] = \begin{cases} 1 & \text{if } C_m(i,j,k) = 1 \\ 0 & \text{otherwise} \end{cases}$$

$$\hat{\mathbf{c}}_m[lin(i,j,k)] = \begin{cases} 1 & \text{if } C_m(i,j,k) \neq invalid \\ 0 & \text{otherwise} \end{cases}$$

$$\hat{\mathbf{c}}_{ab} = \hat{\mathbf{c}}_a \text{AND } \hat{\mathbf{c}}_b$$

$$\mathbf{c}_{a|b} = \mathbf{c}_a \text{ AND } \hat{\mathbf{c}}_{ab} \text{ , } \mathbf{c}_{b|a} = \mathbf{c}_b \text{ AND } \hat{\mathbf{c}}_{ab}$$

$$\gamma_{Bit}(a,b) = \begin{cases} 1 - \frac{\|\mathbf{c}_{a|b} \text{ XOR } \mathbf{c}_{b|a}\|}{\|\mathbf{c}_{a|b}\| + \|\mathbf{c}_{b|a}\|} & \text{if } C_a \text{ and } C_b \text{ are } matchable \\ 0 & \text{otherwise} \end{cases}$$

$\gamma_{Bit}(a,b)=0.63$

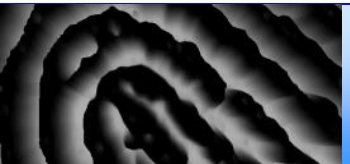
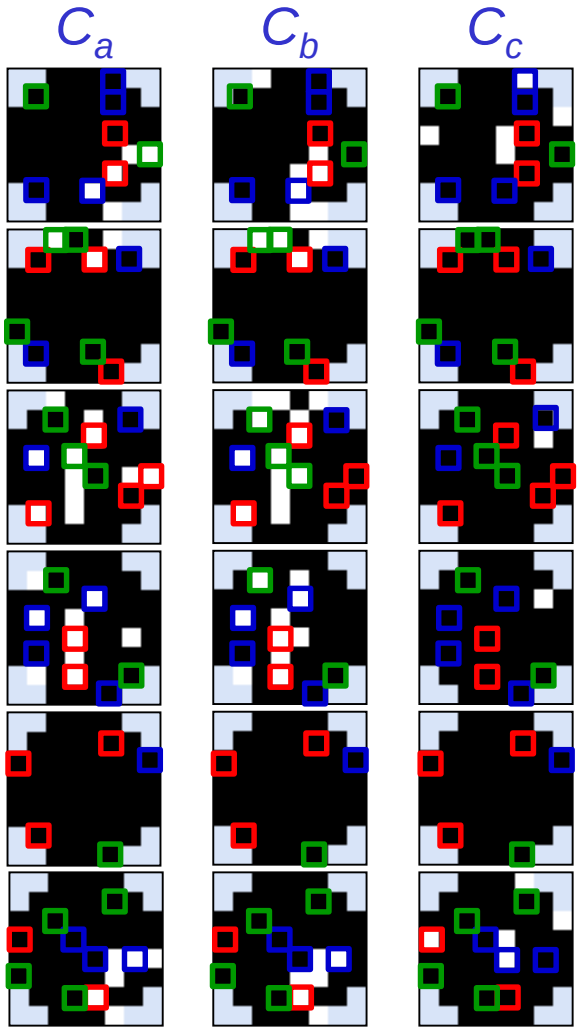
Running MCC on multicore CPU and GPU

Version	System configuration	Test	Matches per second
MCC Matcher (single core, no SSE optimizations) Download the SDK at: http://biolab.csr.unibo.it	Intel CPU E5-2650 @ 2GHz (2 processors), 64 bit O.S.	100 identification queries on a 1M database	5.8 K
MCC SSE4 Optimized Matcher for CPU	Intel CPU E5-2650 @ 2GHz (2 processors, 32 cores), 64 bit O.S.	100 identification queries on a 1M database	5.3 M
MCC GPU (CUDA) and CPU Optimized Matchers	Intel CPU E5-2650 @ 2GHz (2 processors, 32 cores), 4 Nvidia Tesla C2075 GPUs, 64 bit O.S.	100 identification queries on a 1M database	41.7 M

Cappelli, Ferrara & Maltoni, *Large-scale fingerprint identification on GPU* Information Sciences, 2015



Fingerprint indexing based on MCC (1)



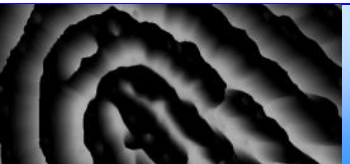
An effective method for indexing binary vectors using Hamming-based metrics is *Locality-Sensitive Hashing* (LSH). LSH is based on the simple idea that if two vectors are similar, then after a "projection" into a lower-dimensional subspace, they will remain similar.

$$H_1 = \{23, 39, 56, 59, 103, 118, 137, 144, 146, 185, 200, 216, 218, 250, 278, 305\}$$
$$H_2 = \{3, 8, 42, 45, 61, 94, 113, 123, 170, 175, 191, 207, 225, 281, 290, 292\}$$
$$H_3 = \{4, 33, 52, 53, 86, 97, 109, 125, 134, 161, 203, 259, 268, 272, 294, 304\}$$

The set of indices defines a hash function that maps a cylinder to the natural number corresponding to its binary representation.

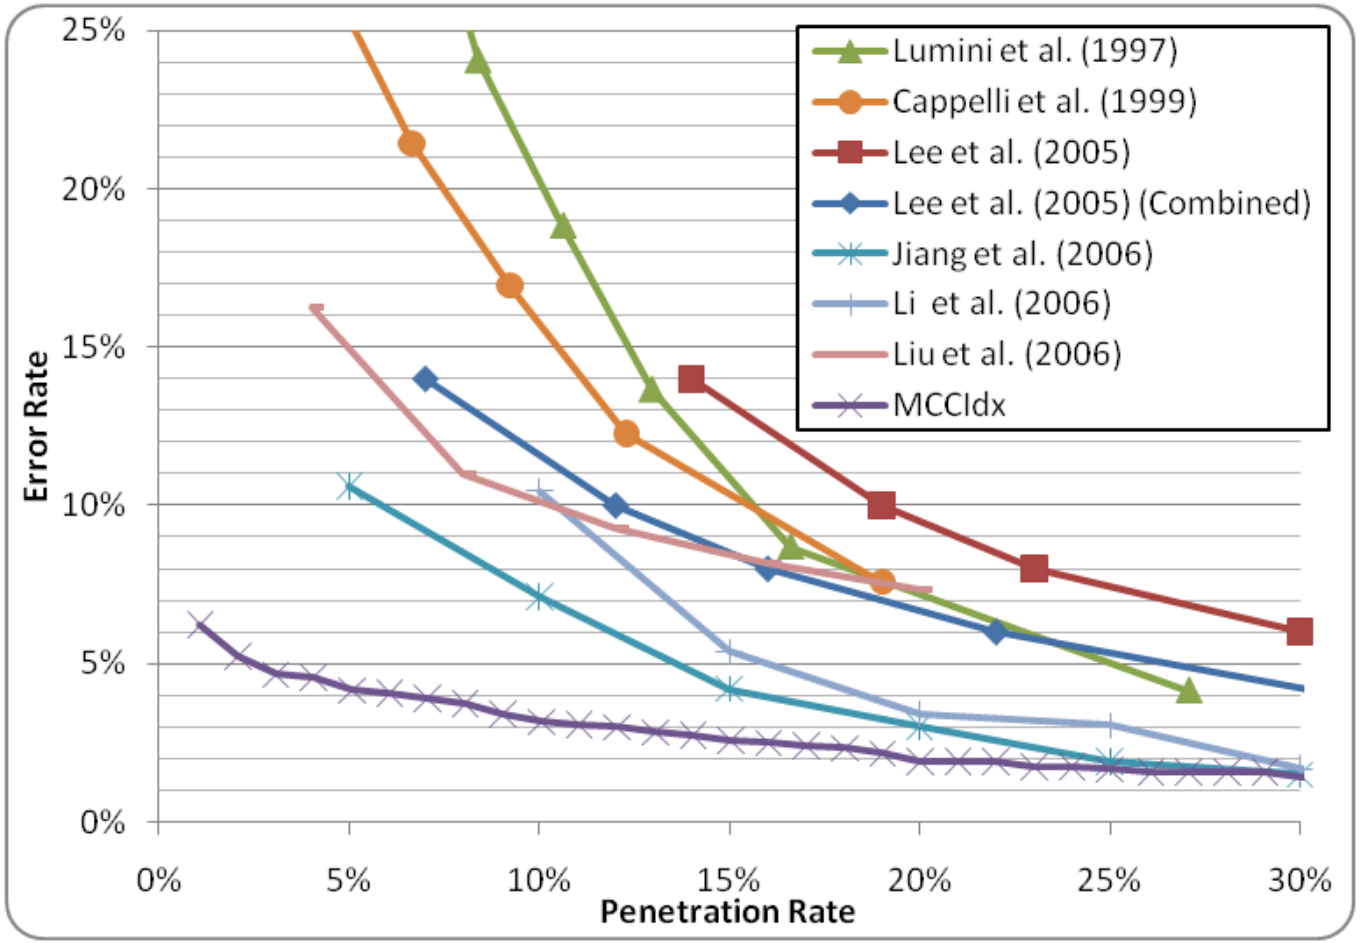
0 1 0 1 0 1 1 0 1 1 1 0 0 0 0 1	$f_{H_1}(C_a) = 22241$
0 1 0 1 0 1 1 0 1 1 1 0 0 0 0 1	$f_{H_1}(C_b) = 22241$
0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0	$f_{H_1}(C_c) = 2$
0 0 0 1 0 0 0 1 1 1 0 0 0 0 0 1	$f_{H_2}(C_a) = 4545$
0 0 0 1 0 0 0 1 1 1 0 0 0 0 0 1	$f_{H_2}(C_b) = 4545$
1 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0	$f_{H_2}(C_c) = 32770$
0 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0	$f_{H_3}(C_a) = 24832$
0 0 1 1 0 0 1 1 1 1 0 0 0 0 0 0	$f_{H_3}(C_b) = 13248$
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	$f_{H_3}(C_c) = 0$

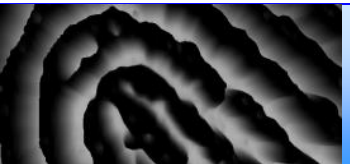
Then the similarity between two cylinders can be simply estimated by counting the number of collisions under the various hash functions.



Fingerprint indexing based on MCC (2)

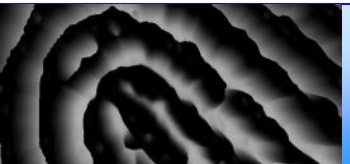
Results on NIST DB4





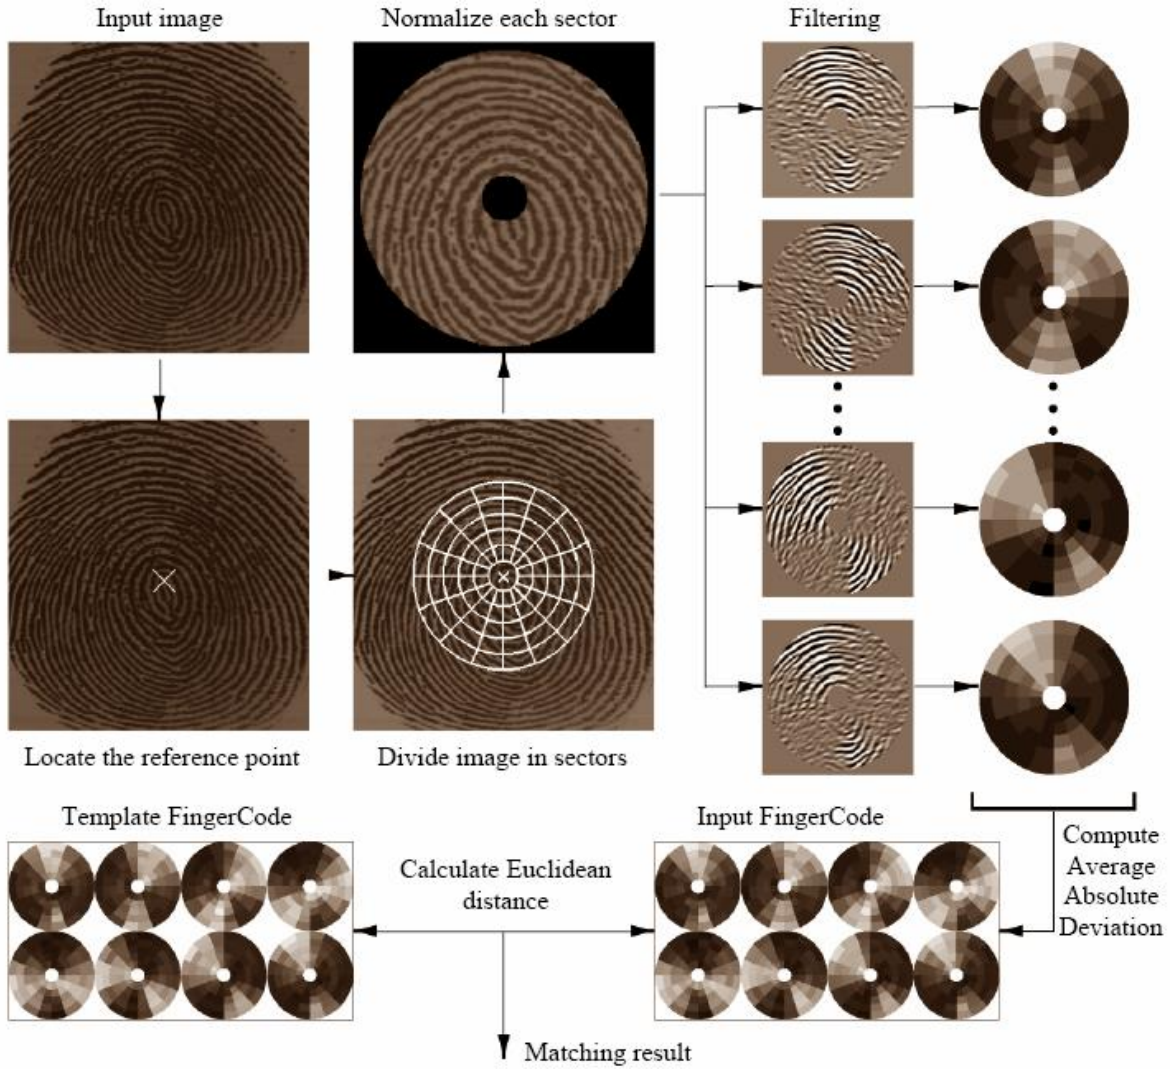
Ridge feature-based matching

- Why other features and not simply minutiae ?
  - reliably extracting minutiae from poor quality fingerprints is very difficult
  - a fixed-length invariant feature code is useful for "indexing" fingerprint databases
  - additional features may be used in conjunction with minutiae (and not as an alternative) to increase system accuracy and robustness
- The most commonly used alternative features are:
  1. size of the fingerprint and shape of the external fingerprint silhouette;
  2. number, type, and position of singularities;
  3. spatial relationship and geometrical attributes of the ridge lines (Xiao and Bian (1986) and Kaymaz and Mitra (1992));
  4. shape features (Takeda et al. (1990) and Ceguerra and Koprinska, 2002);
  5. global and local texture information;
  6. sweat pores (Stosz and Alyea, 1994);
  7. fractal features (Polikarpova, 1996).



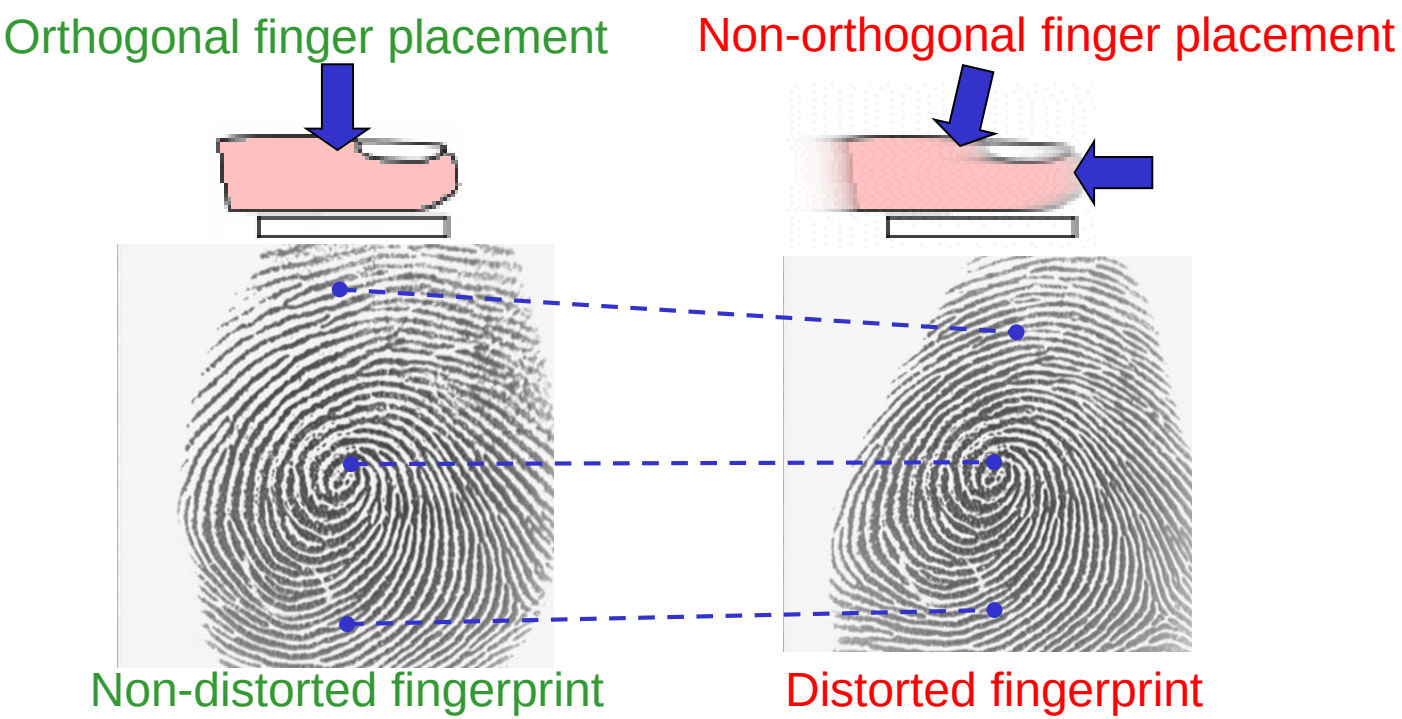
Texture-based matching

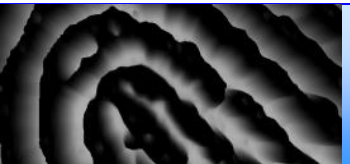
FingerCode approach (Jain et al. (2000))



Skin distortion

One of the main factors that contribute to make substantially different the impressions of a given finger is skin distortion





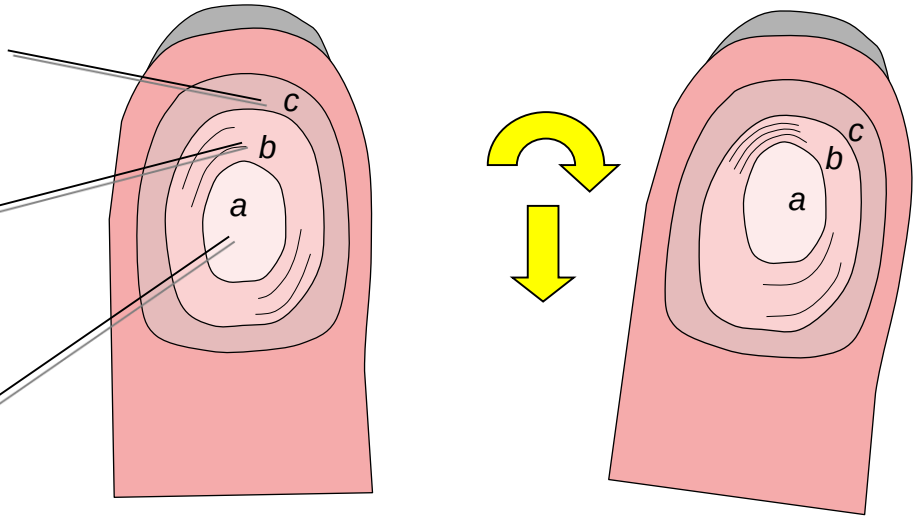
Skin distortion model (1)

The finger pressure against the sensor is not uniform, but decreases moving from the center towards the borders.

external region: skin moved

transitional region: skin distorted

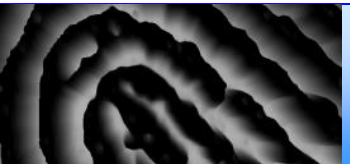
close-contact region: skin not moved



a) close-contact region, where the high pressure and the surface friction does not allow any skin slippage

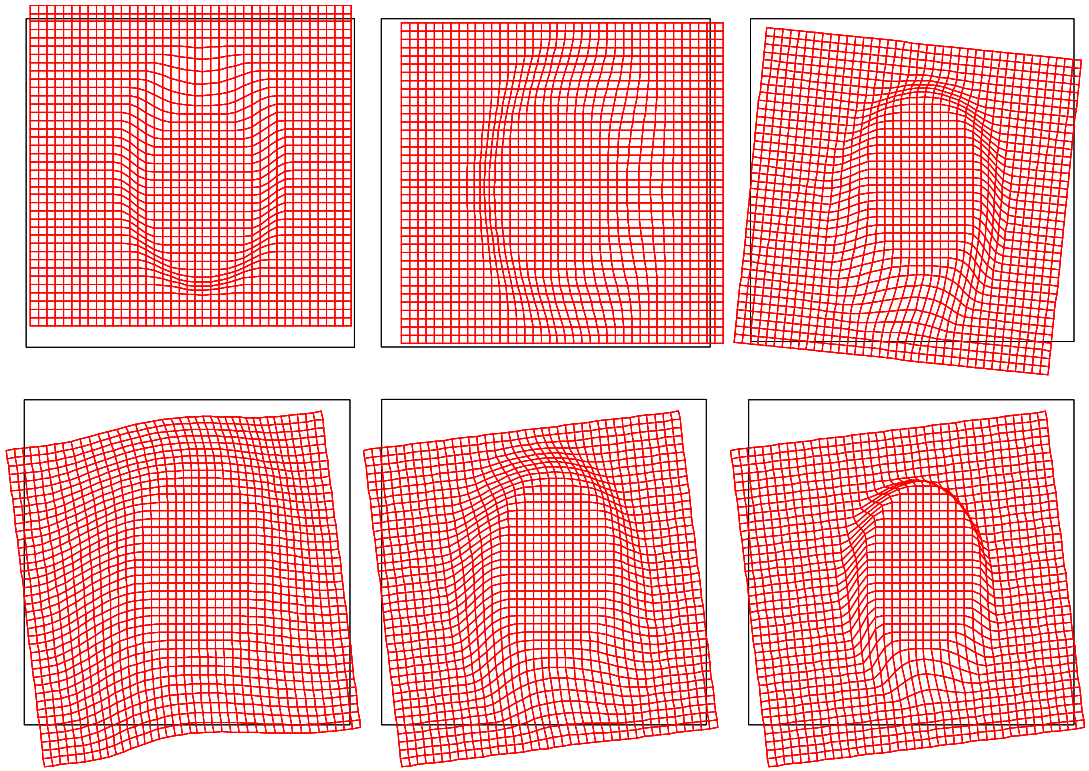
c) external region, where the low pressure allows the skin to be dragged by the finger movement

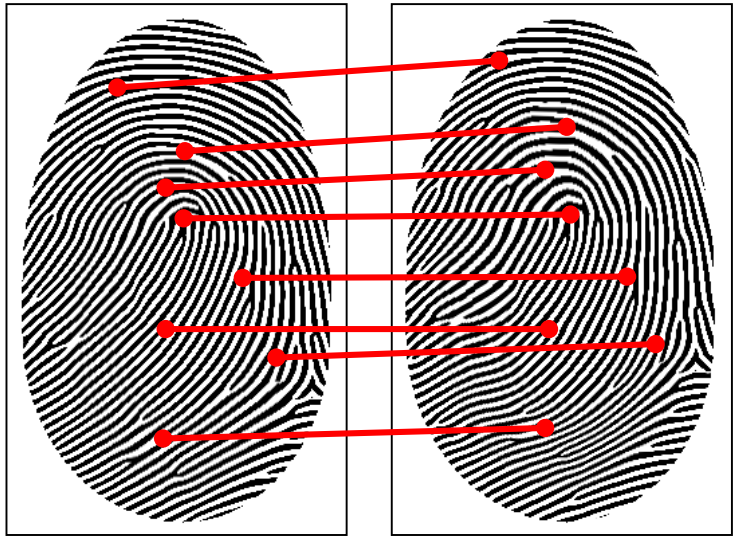
b) transitional region where an elastic distortion is produced to smoothly combine regions *a* and *c*



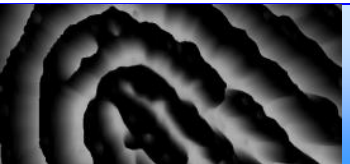
Skin distortion model (2)

$$distortion : \Re^2 \rightarrow \Re^2, \quad distortion(\mathbf{v}) = \mathbf{v} + \Delta(\mathbf{v}) \cdot brake(shapedist_a(\mathbf{v}), k)$$





Original image Distorted image

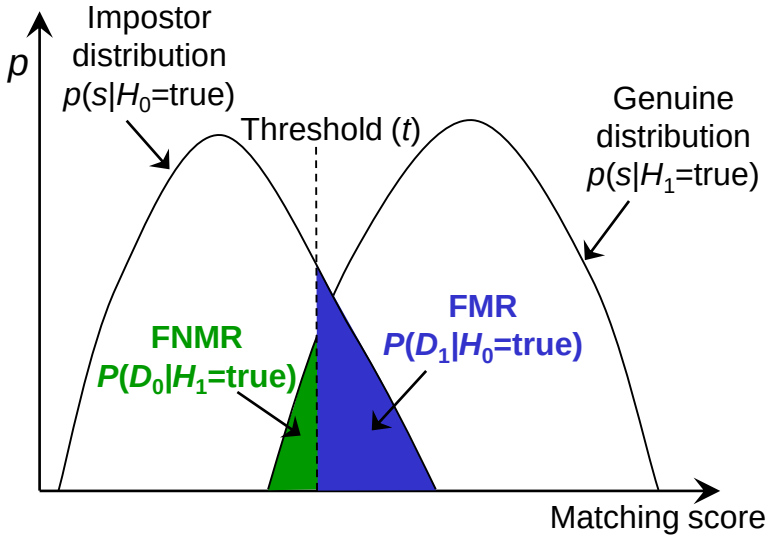


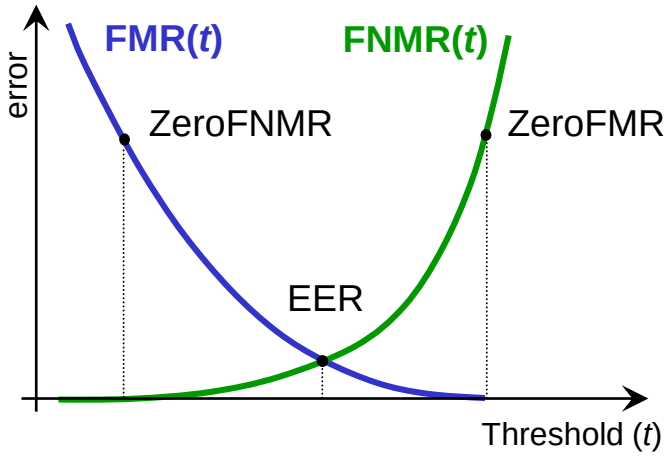
Performance evaluation: errors

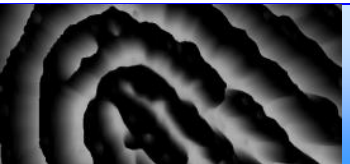
- False Match (in positive recognition often called False Acceptance)
  - mistaking biometric measurements from two different persons to be from the same person
- False Non-Match (in positive recognition often called False Rejection)
  - mistaking two biometric measurements from the same person to be from two different persons

Hypotheses:
H_0: different person
H_1: same persons

Possible decisions:
D_0: different person
D_1: same persons



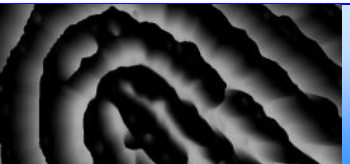




Fingerprint Verification Competitions

Algorithms are provided as binary executable programs, compliant to a given I/O protocol

- FVC is a technology evaluation of algorithms
  - Not complete systems, but only algorithms
  - Not a performance evaluation in a real application
- Main aims
  - Track the state-of-the-art in fingerprint recognition
  - Provide updated benchmarks and a testing protocol for fair and unambiguous evaluation of fingerprint verification algorithms

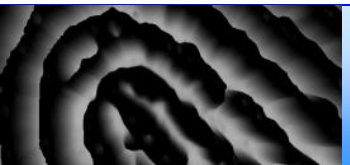


FVC Competitions – Summary

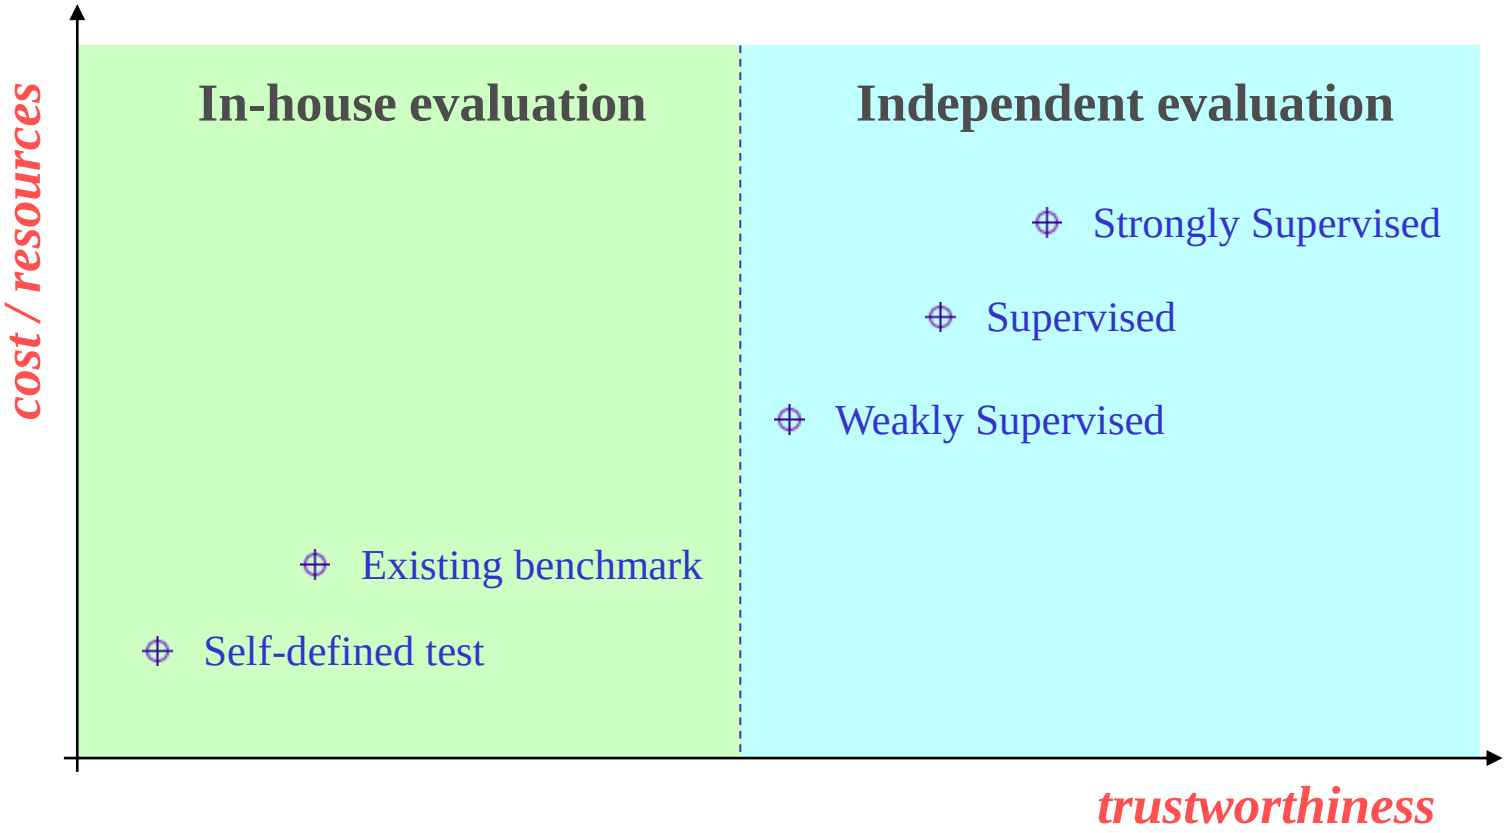
	FVC2000	FVC2002	FVC2004	FVC2006
Participants registered	**25**	**48**	**110**	**150**
Actual participants	**10**	**28**	**43**	**53**
Algorithms evaluated	**11**	**31**	**41 (*Open*) 26 (*Light*)**	**44 (*Open*) 26 (*Light*)**
Website accesses	~60,000	~60,000	~60,000	~20,000
E-mails exchanged	>500	>700	>900	>800
Databases	4 (set A: 100x8 fingerprints, set B: 10x8 fingerprints)			4 (set A: 140x12 fingerprints, set B: 10x12 fingerprints)

FVC onGoing

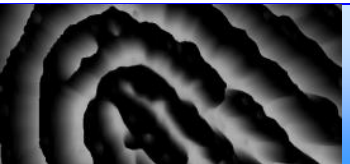
2009 … still running



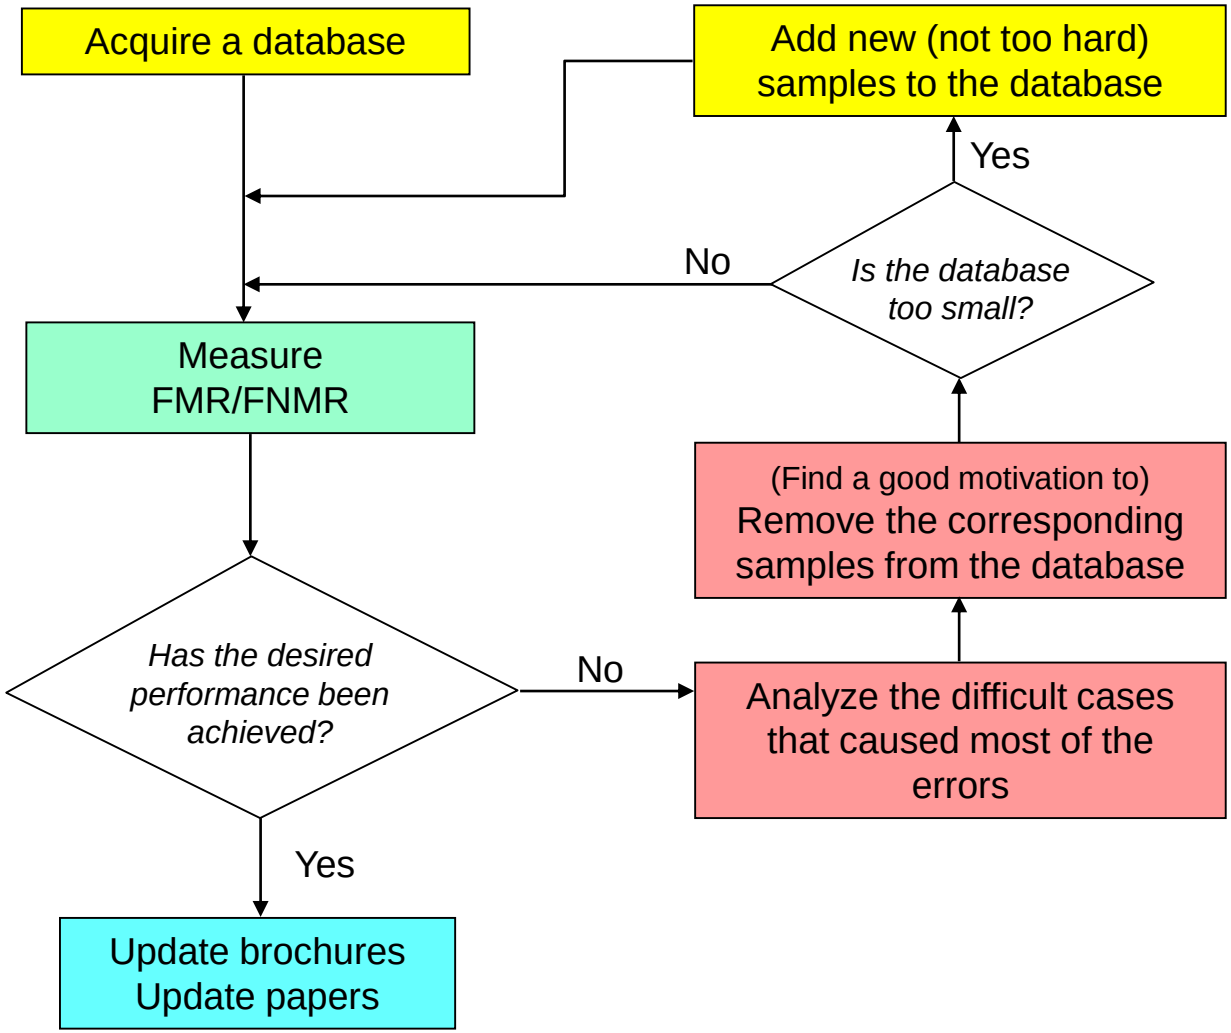
Technology evaluations

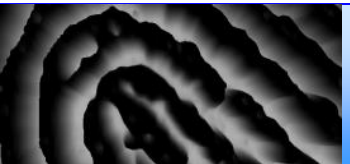


For details see: See R. Cappelli, D. Maio, D. Maltoni, J.L. Wayman and A.K. Jain, Performance Evaluation of Fingerprint Verification Systems, IEEE Transactions on Pattern Analysis Machine Intelligence, vol.28, no.1, pp.3-18, January 2006.



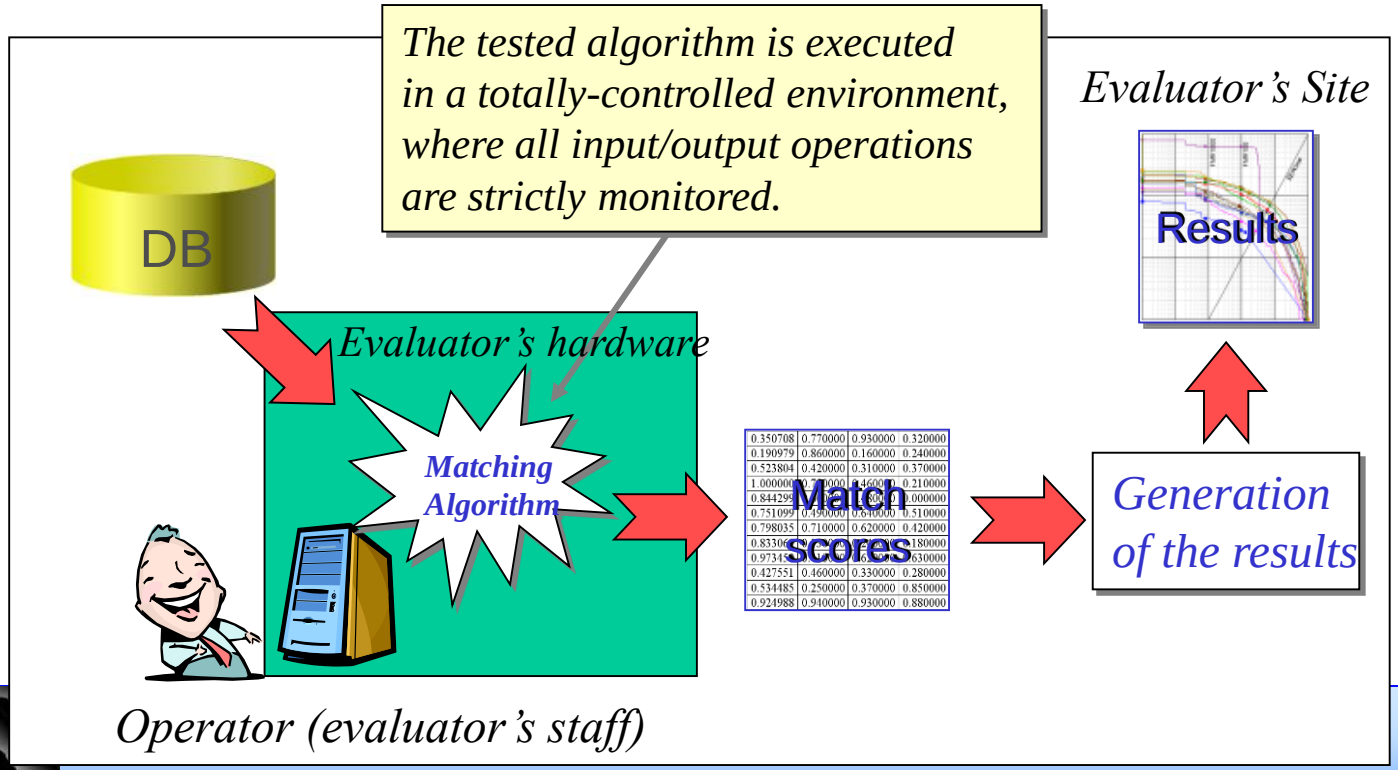
The risk of in-house testing with self-defined protocols





FVC Testing procedure

- **Database**: sequestered data
- **Protocol**: software components compliant to a given input/output protocol are tested on the evaluator's hardware
- **Results**: generated by the evaluator from the matching scores obtained during the test

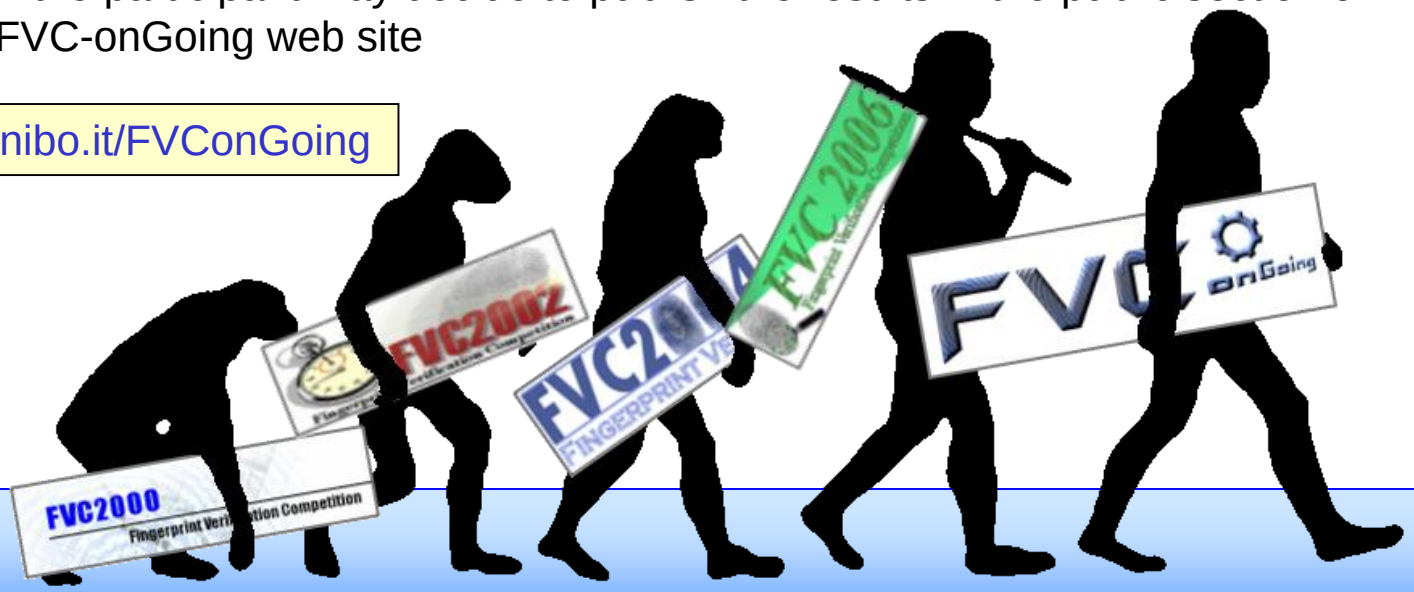


FVC-onGoing

started June 2009

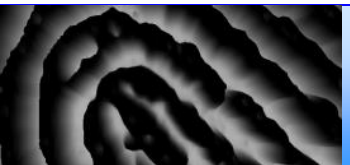
- Web-based automatic evaluation of fingerprint recognition algorithms
  - Participants can be: companies, academic research groups, or independent developers
  - Algorithms are tested on sequestered datasets and results are reported using well-known performance indicators and metrics
  - Fully automated:
    1. The system automatically tests the algorithm submitted by a participant
    2. The participant sees the results in its “private area”
    3. Then the participant may decide to publish the results in the public section of the FVC-onGoing web site

http://biolab.csr.unibo.it/FVConGoing

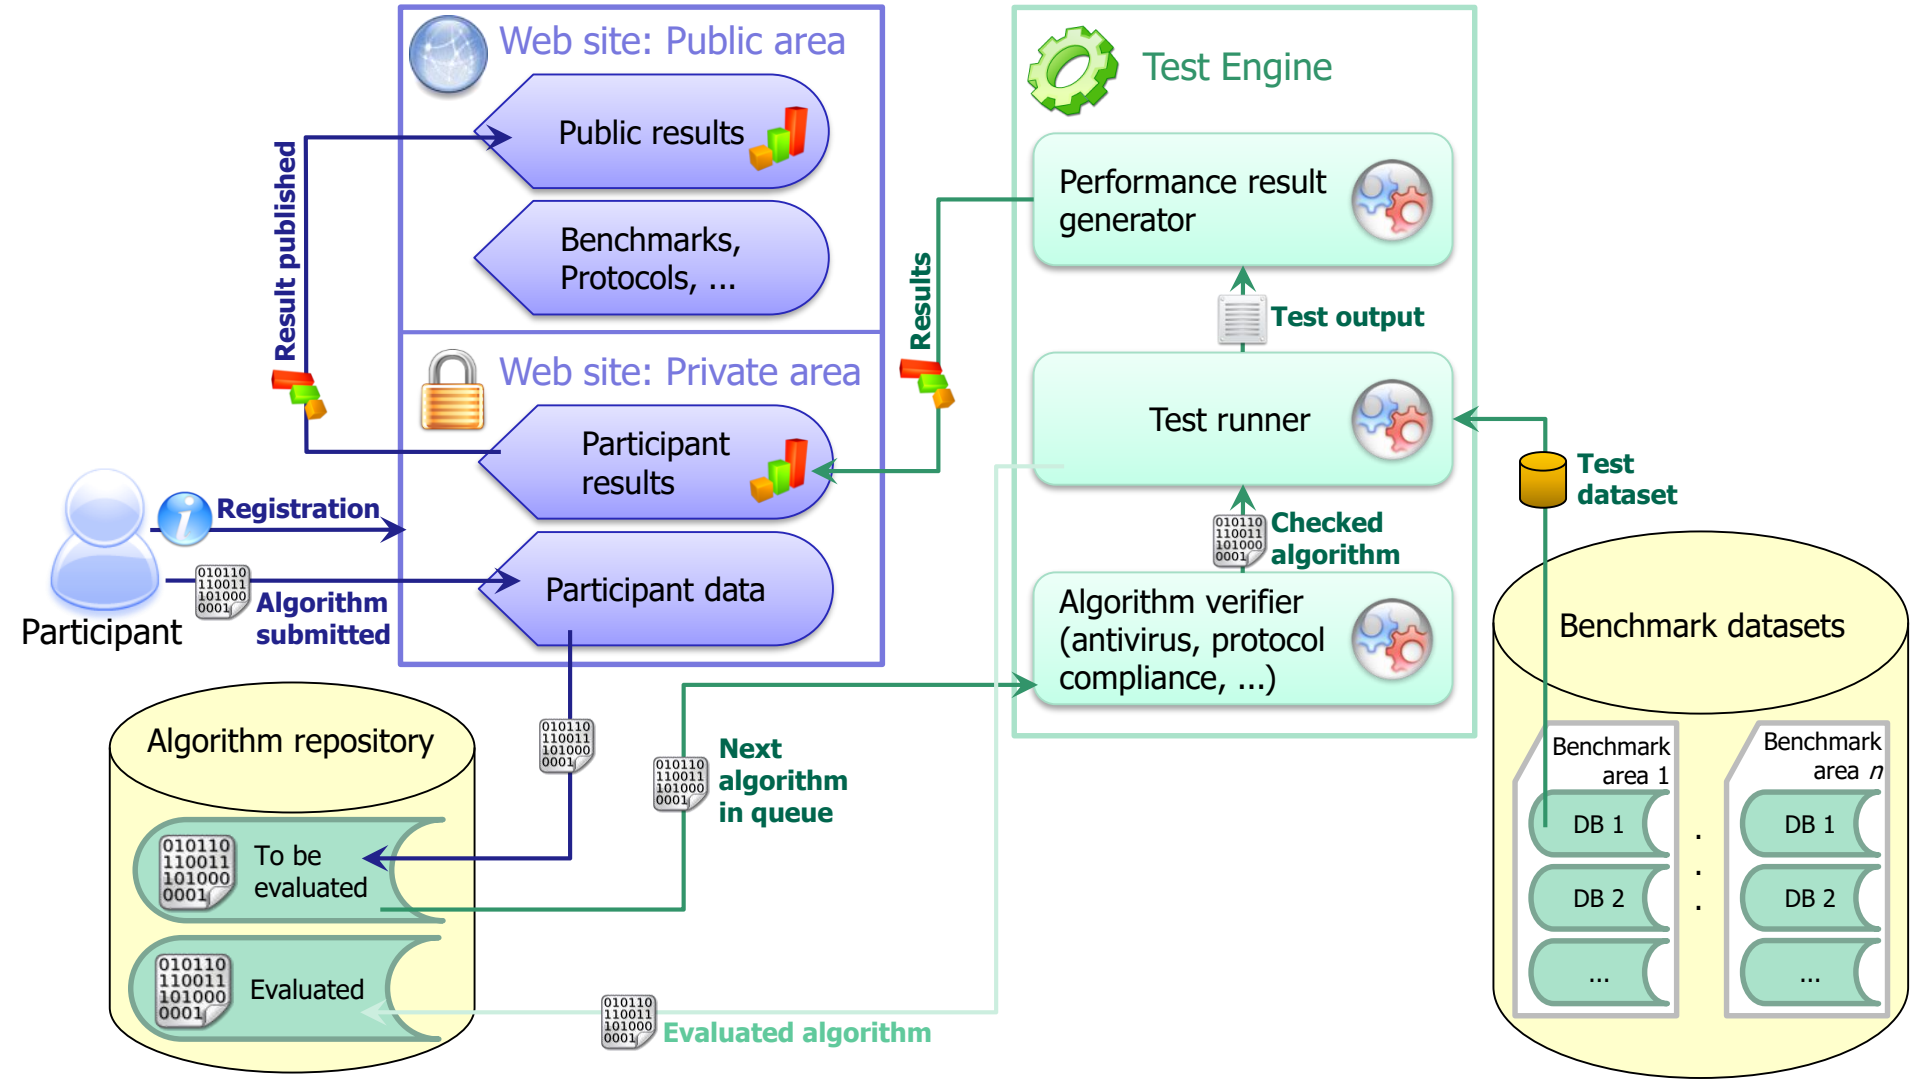


What's new in FVC-onGoing

- Previous FVC initiatives were organized as "competitions"
  - Specific calls and Fixed time frames
- FVC-onGoing is:
  - An "on going competition" always open to new participants
    - Datasets will remain sequestered
  - An evolving online repository of benchmarks, evaluation metrics and results
    - However the benchmark datasets will not evolve over time; in case new datasets will be added in the future, they will form a different benchmark (or a new version of an existing one)
- Not only limited to fingerprint verification algorithms:
  - Ad hoc benchmarks for testing specific modules of fingerprint verification systems will be available, for instance:
    - Orientation Image Estimation
    - Minutiae Extraction

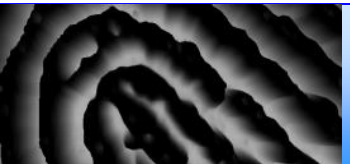


FVC-onGoing: Workflow



Former benchmarks

Area	Benchmark	Description
 **FV** Fingerprint Verification	FV-TEST	A simple dataset useful to test algorithm compliancy with the testing protocol
	FV-STD-1.0	Fingerprint images acquired in operational conditions using high-quality optical scanners
	FV-HARD-1.0	Difficult cases (noisy images, distorted impressions, etc.): more challenging
 **FMISO** Fingerprint ISO Template Matching	FMISO-TEST	A simple dataset useful to test algorithm compliancy with the testing protocol
	FMISO-STD-1.0	Fingerprint images acquired in operational conditions using high-quality optical scanners
	FMISO-HARD-1.0	Difficult cases (noisy images, distorted impressions, etc.): more challenging
 **FOE** Fingerprint Orientation Extraction	FOE-TEST	A simple dataset useful to test algorithm compliancy with the testing protocol
	FOE-STD-1.0	Orientation extraction benchmark on fingerprints with orientation ground-truth manually labeled using an ad-hoc software tool. Good-quality and bad-quality datasets.



Current status (May 2018)

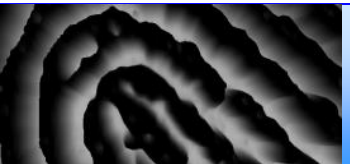
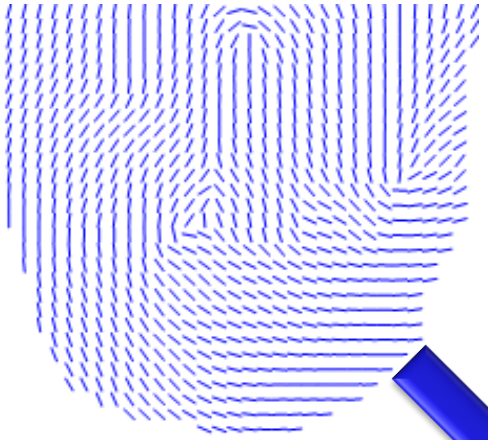
For the most effective algorithms
enhancement / binarization based on contextual filtering
alignment mainly relies on minutiae
matching with multiple features (minutiae, frequency, orientation)
minutia alignment/matching with two stage: local matching + global consolidation



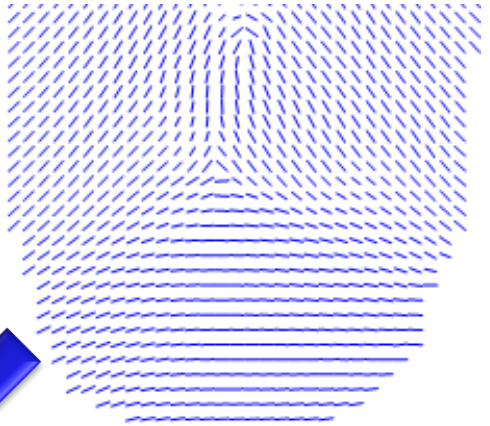
Fingerprint Orientation Extraction

- Challenge: Estimation of local orientations in low-quality images
  - A fundamental step in fingerprint analysis and recognition



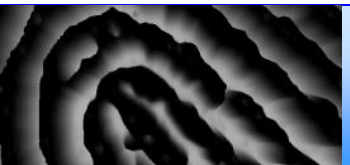
Typical approach

Ideal result



Enhancement based on the estimated orientations

Enhancement based on the true orientations



Evaluating Fingerprint Orientation Extraction

- How the benchmark works:
  - Participants' algorithms are required to extract local orientations from fingerprint images and to save them into a specific format.
  - The extracted orientations are compared to the **ground-truth** in order to assess the algorithm accuracy.

Fingerprint

Ground truth

Extracted

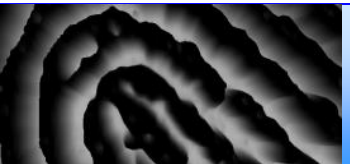
Next steps

- Recently-added benchmark areas
  - Fingerprint Orientation Extraction
  - Secure-Template Fingerprint Verification
  - Fingerprint Indexing
  - Palmprint verification (Tsinghua University)
  - Face Image ISO Compliance Verification
  - Face Morphing Challenge

- New benchmark areas planned
  - Fingerprint Identification (1:N)
  - Minutiae extraction accuracy

NIST evaluations on fingerprints

- **FpVTE** (Fingerprint Vendor Technology Evaluation)
  - FpVTE 2003 (http://www.nist.gov/itl/iad/ig/fpvte03.cfm)
    Best single-finger system: FRR < 1.4% @ FAR = 0.01%
  - FpVTE 2012 (http://www.nist.gov/itl/iad/ig/fpvte2012.cfm)
    Test identification systems (1:N), with N = several millions
- **PFT** (Proprietary Fingerprint Template): proprietary (non interoperable) SDK
  - PFT (2003), PFT II (2010)
- **MINEX** (Minutiae Exchange Test): minutiae-based interoperable templates
  - MINEX 2004
  - Ongoing MINEX: for PIV interoperability
  - MINEX II: Match-on-Card evaluation
- **ELFT** (Evaluation of Latent Fingerprint Technologies): for AFIS and latent fingerprints
  - ELFT (2008)
  - ELFT-EFS (Extended Feature Sets): test extended features (eg. minutiae + pores)



Operational evaluation: UIDAI

- **UIDAI (2012)**: one of the most ambitious biometric projects.

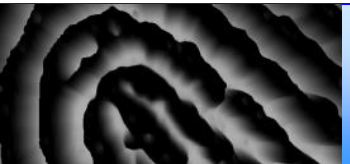
  All Indian residents (about 1.2 billions) are being enrolled and provided with a unique 12 digits identification code (AADHAAR):

  - 10 fingerprints, 2 irises, face stored in a central DB
  - AADHAAR released after Duplicate Enrolment Check (1:N)
  - 36000 enrolment sites (including isolated villages)
  - 1.19 billion enrolments performed @ Nov 2017

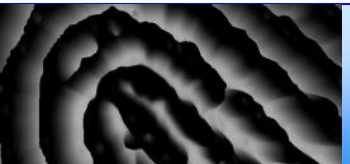
- **Multi-biometric, multi-vendor** (L1, Morpho, Nec) **ABIS**:

  Statistics @ 2012

  - Failure To Enrol (FTE) = 0.14%
  - $FRR_{1:N}$ (falsely denoted as duplicated due to False Match): 0.057%
  - $FAR_{1:N}$ (missed due to False Non-Match): 0.035%

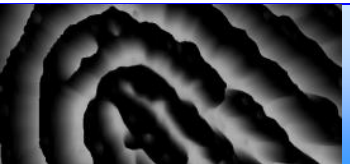


End of part one: state-of-the-art



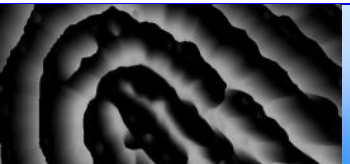
New directions (1)

- Nowadays research on fingerprints is active on:
  - Semi-automated and Automated Latent processing and matching
    - Operating in "light-out" mode is one the major objectives of FBI's Next Generation Identification (NGI) program.
    - Robust context extraction through dictionary of patches
    - Deep learning approaches for local orientation and minutiae extraction
  - Fast fingerprint matching and indexing (millions of fingerprints)
    - New very large AFIS: Indian UIDAI (enrolling 1.2 billions residents), European BMS (for the new Visa Information System)
    - Increasing demand for low cost AFIS from emerging countries
  - Template protection techniques
    - Aim: avoid disclosure of personal data, making compromised templates revocable
    - FVC-onGoing benchmark and MCC-based technique (P-MCC)



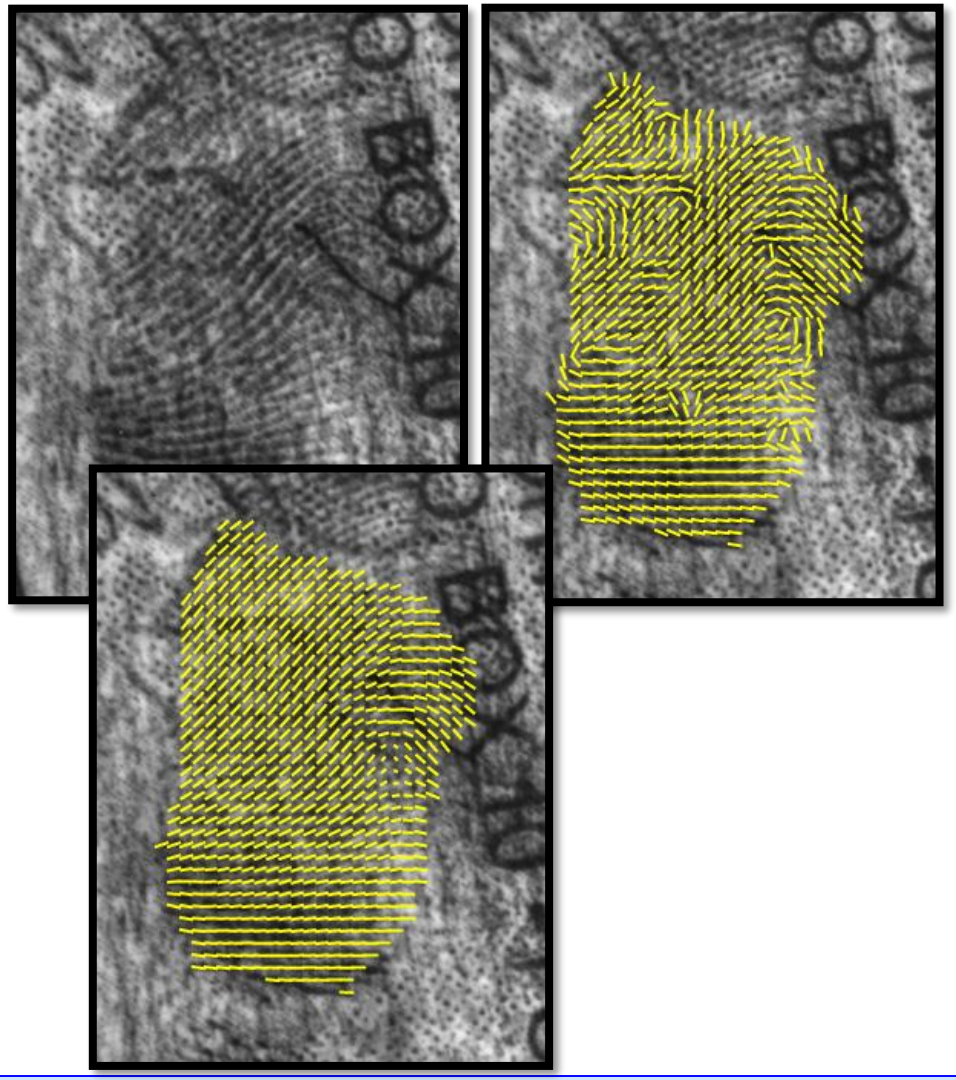
New directions (2)

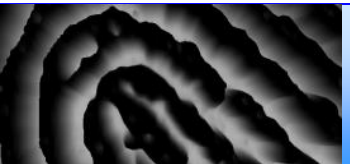
- (…continued from previous slide)
  - New scanning techniques & fake fingerprint detection
    - Sensing under the surface: Optical Coherence Tomography, new ultrasound devices, etc. [Ingress - EU project]
    - Fingerphoto recognition
    - Embedding transparent fingerprint sensors in the smartphone glass
  - Predicting fingerprint recognition accuracy with synthetic data
    - Synthetic dataset of 10M fingerprints generated in [Fidelity - EU project]
  - Double identity fingerprints
    - Mixing features from two different fingers



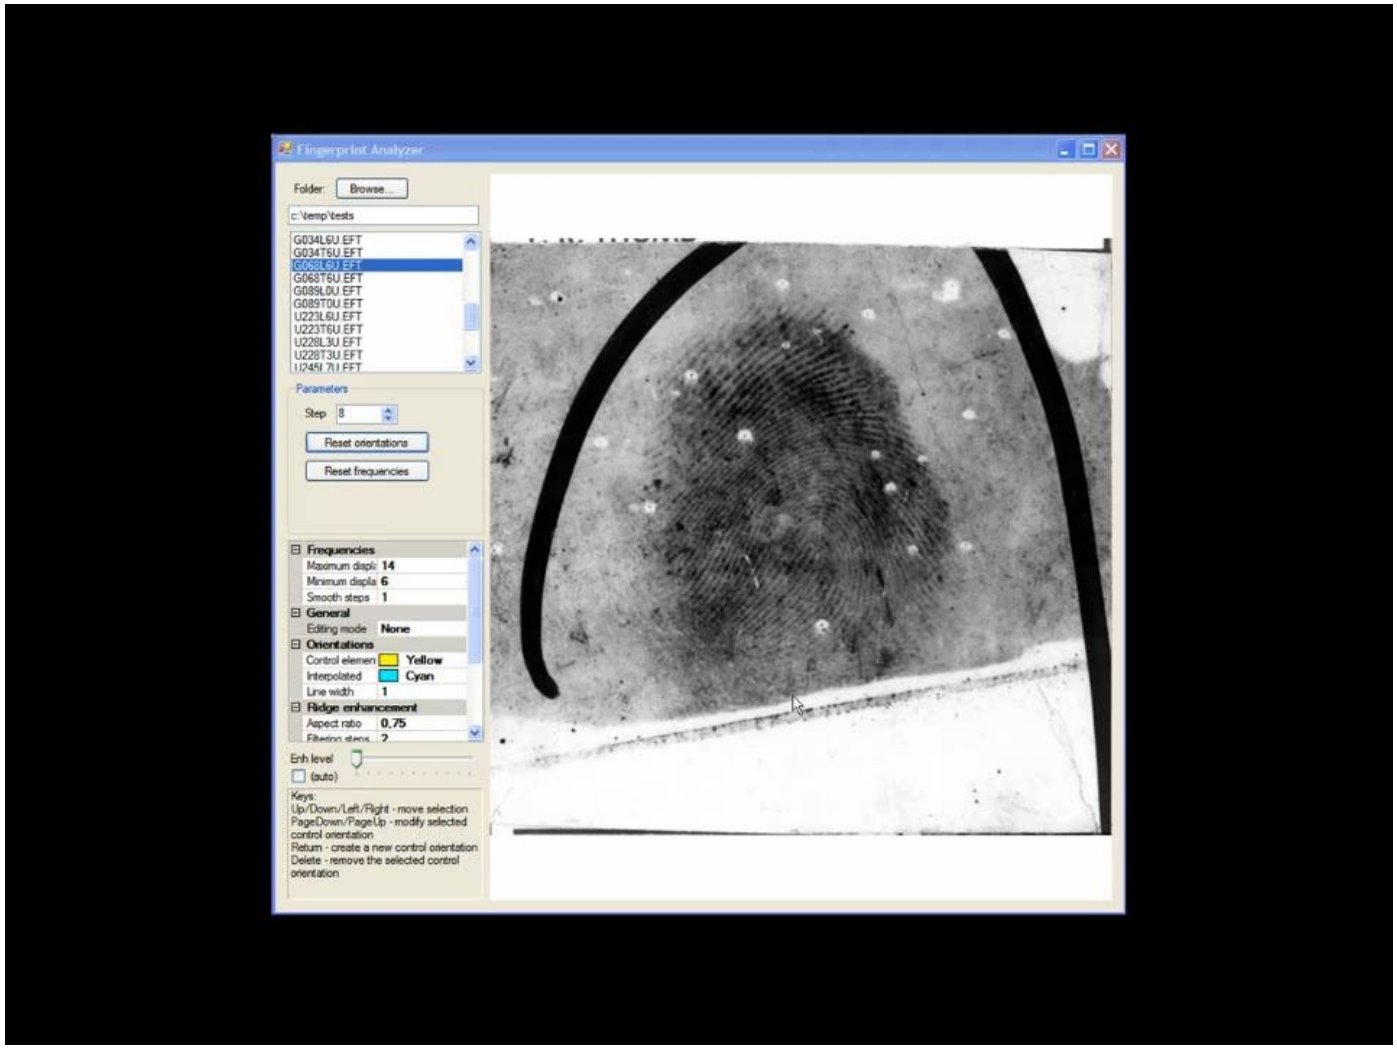
Enhancement of latent fingerprints

- A very challenging task
- How to (automatically) estimate the context?
  - Can local orientations and frequencies be reliably computed on very low-quality fingerprints?
  - Regularization techniques and global orientation models may help to find a solution, but the problem is still open.

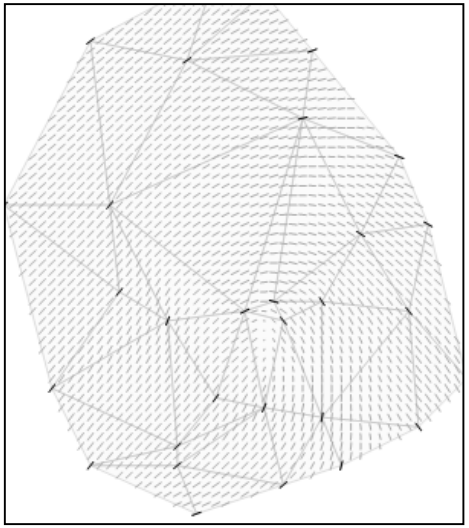


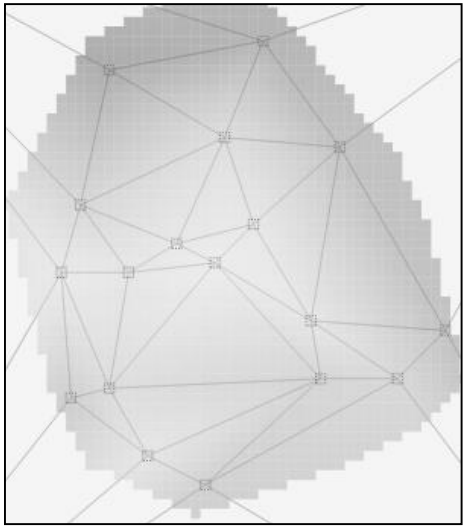


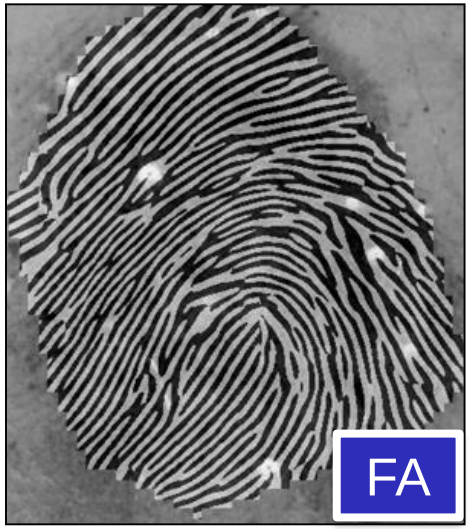
A semi-automatic approach

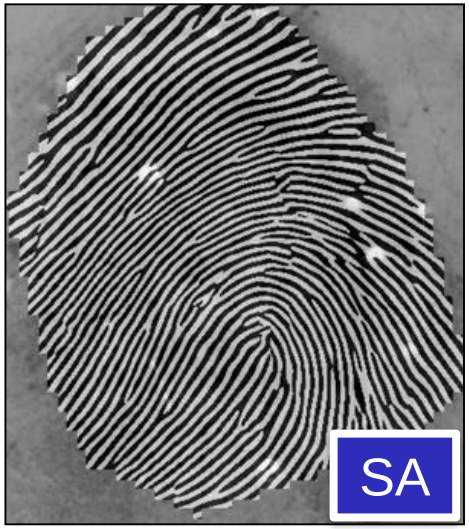


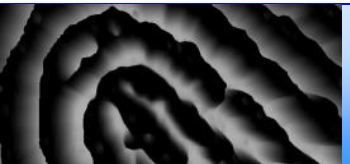
Example: a NIST DB27 “good” latent image



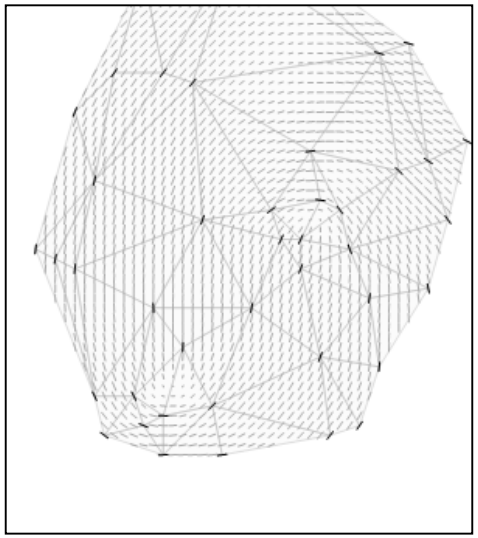


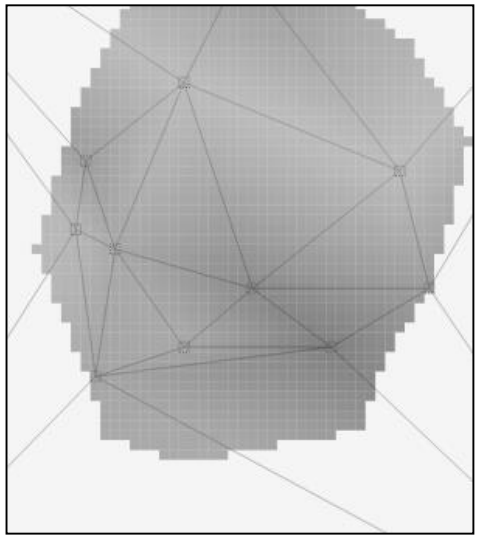


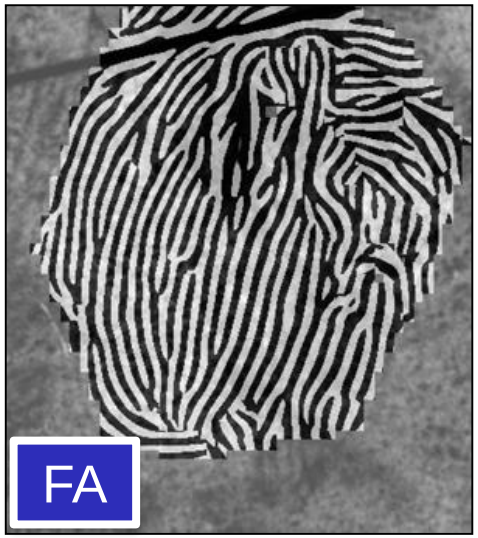


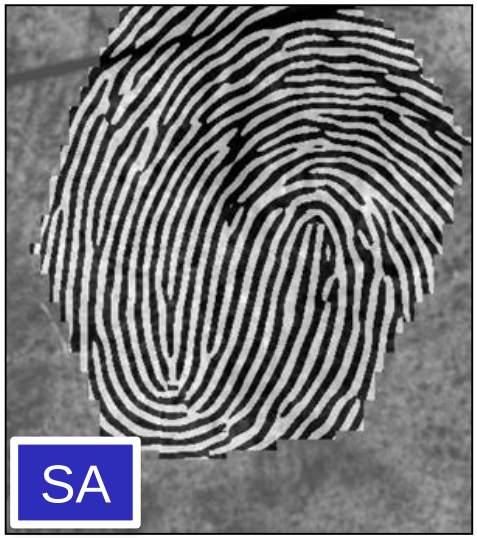


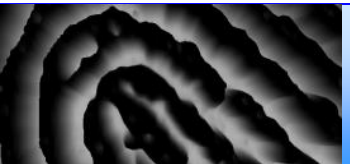
Example: a NIST DB27 “bad” latent image



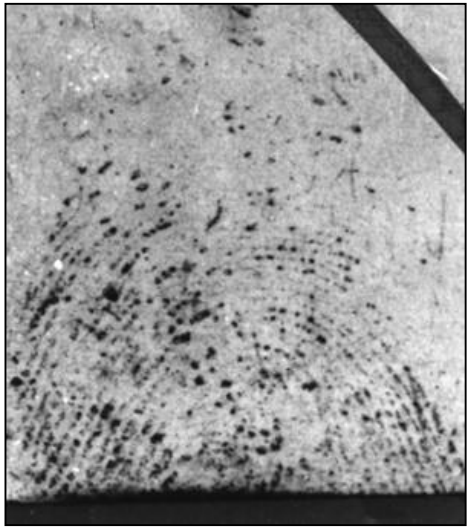


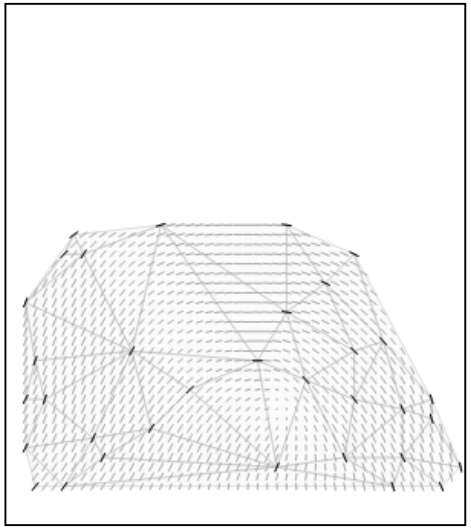


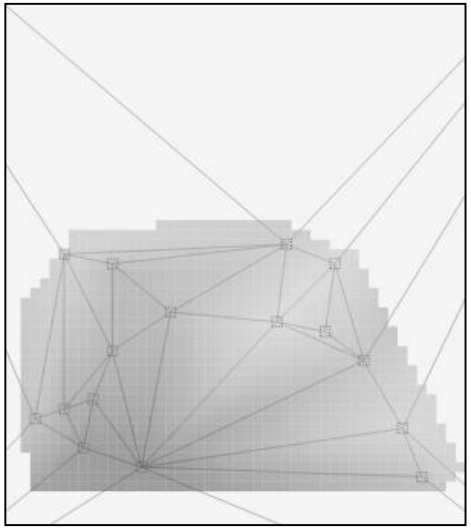


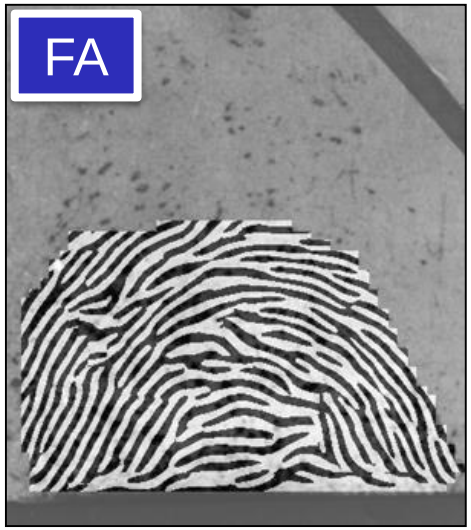


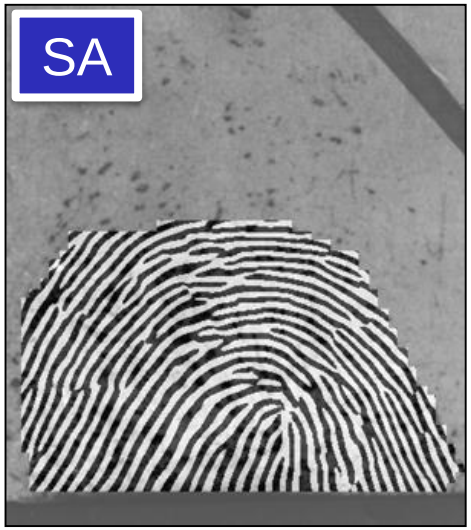
Example: a NIST DB27 “ugly” latent image

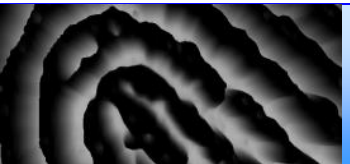












Automatic Latent Processing

- Fully automatic ("lights-out") and highly accurate latent matching is one the major objectives of FBI's Next Generation Identification (NGI) program.
  - Automatic Minutiae extraction on noisy fingerprints is still a problem
    - Segmentation
    - Orientation and Frequency Estimation

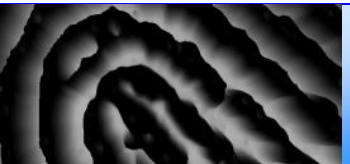
K. Cao and A. K. Jain, "Automated Latent Fingerprint Recognition", IEEE tPAMI, 2018

- Machine learning techniques are being introduced:

  2012…2014: dictionary-based techniques to estimate orientation field

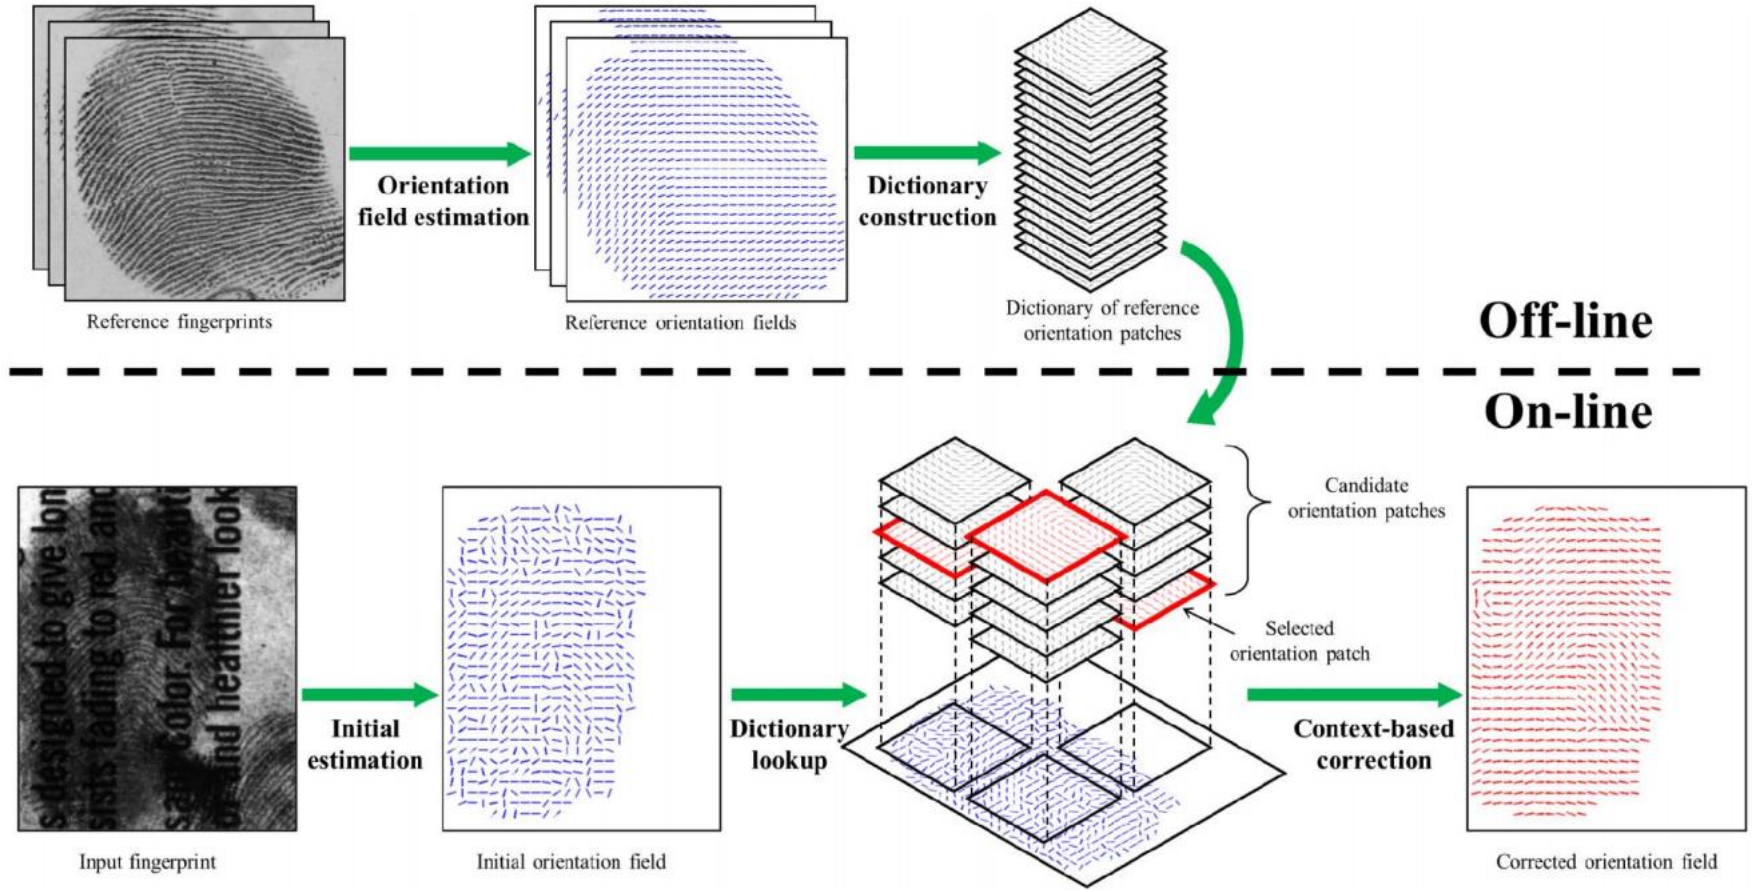
  2014…2018: deep learning approaches:

  - CNN (Convolutional Neural Networks) for orientation extraction, minutiae extraction, minutiae filtering and minutiae descriptors.
  - Autoencoders (denoising), GAN (Generative Adversarial Networks)



Global Orientation Dictionary

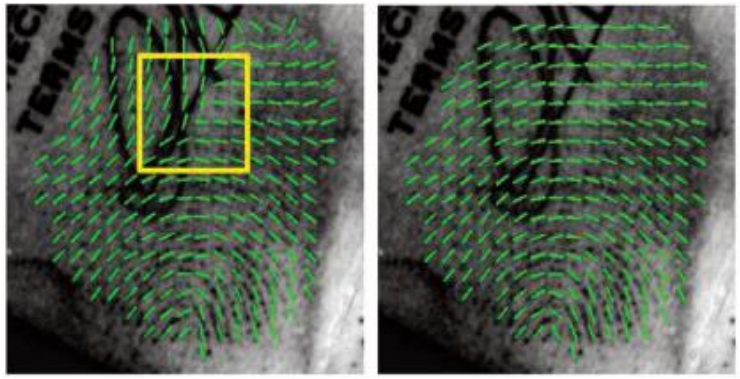
J. Feng, J. Zhou, and A. K. Jain, "Orientation Field Estimation for Latent Fingerprint Enhancement", IEEE Trans. PAMI, 2013.



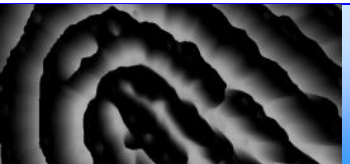
Local Orientation Dictionary

X. Yang, J. Feng and Jie Zhou, “Localized Dictionaries Based Orientation Field Estimation for Latent Fingerprints”, IEEE Trans. PAMI, 2014.

- In the global approach, since the positions of the patches have not been restrained, some orientation patches may occur at impossible locations.



- Localizing patches by using localized dictionaries is a natural extension, but the fingerprint has to be pre-aligned; in [B] robust registration algorithm based on probabilistic voting of all local orientation patches.
- The local dictionary approach outperformed the global one in a number of experiments and is currently the best-performing approach in the FvcOnGoing FOE (Fingerprint Orientation Estimation) benchmark.

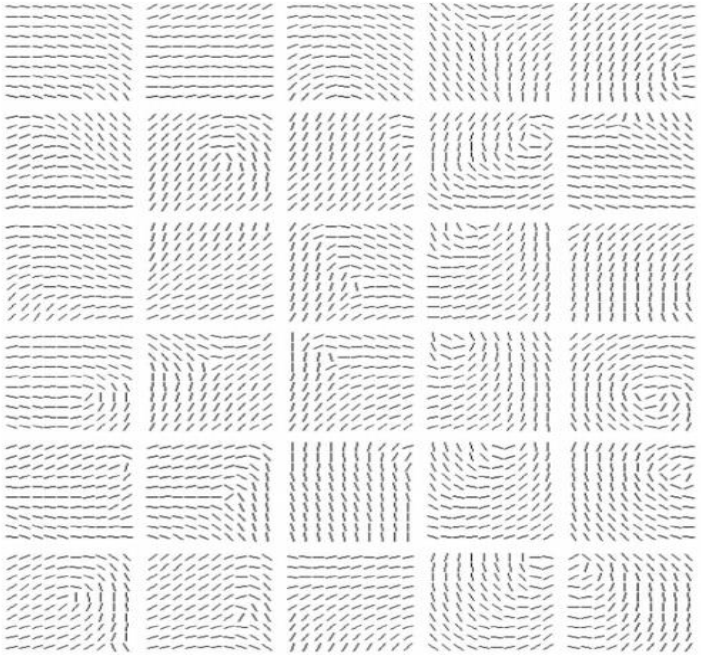


Ridge Structure Dictionary

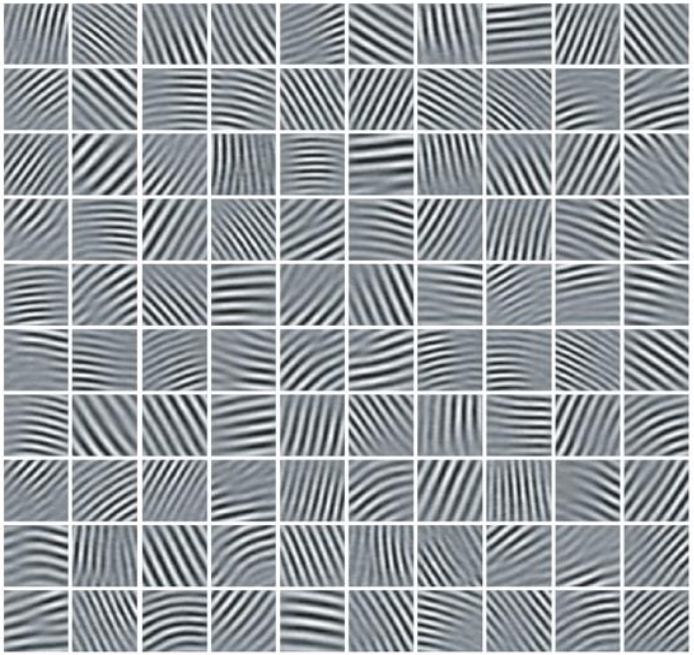
K. Cao, E. Liu and A. K. Jain, "Segmentation and Enhancement of Latent Fingerprints: A Coarse to Fine Ridge Structure Dictionary", IEEE Trans. PAMI, 2014.

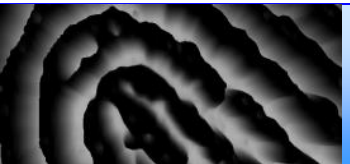
- Ridge-frequency can be estimated as well.

Orientation patches



Ridge structure patches

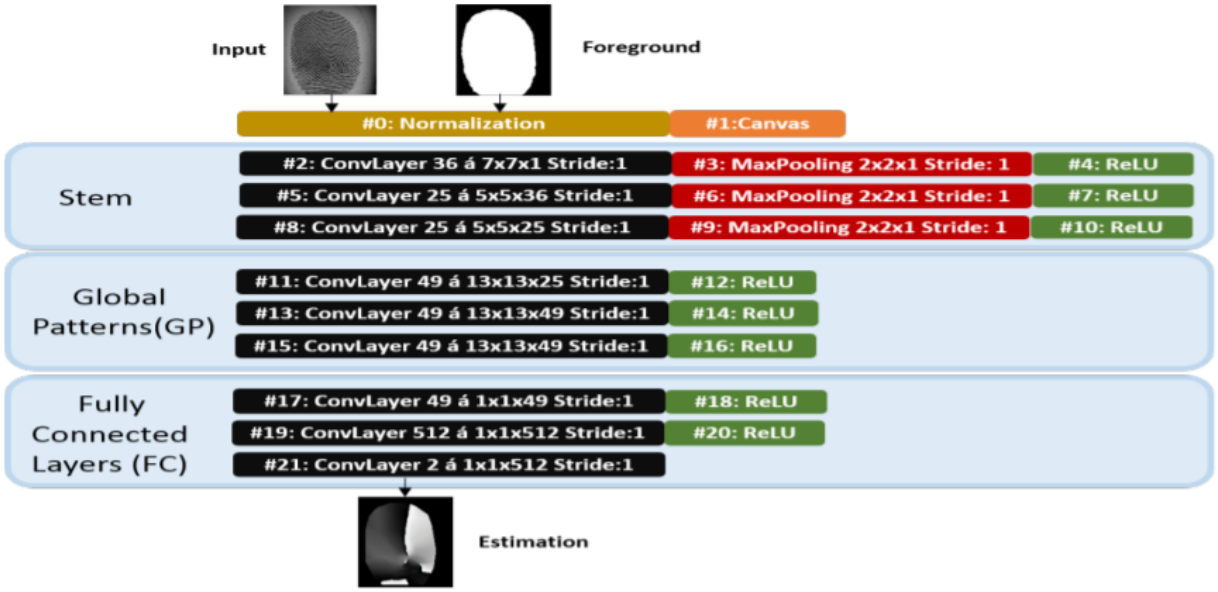


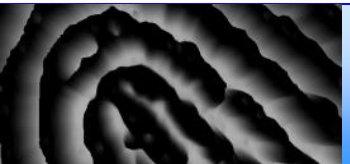


Orientation Extraction with CNN

P. Schuch, S. D. Schulz and C. Busch, "Deep expectation for estimation of fingerprint orientation fields," IJCB, Denver, CO, 2017.

- Best Performing Approach (May 2018) on FVC-onGoing FOE
- In principle orientation estimation is a regression problem, but classification often proved to be better.
- Deep Expectation: weighted mean instead of winner take all

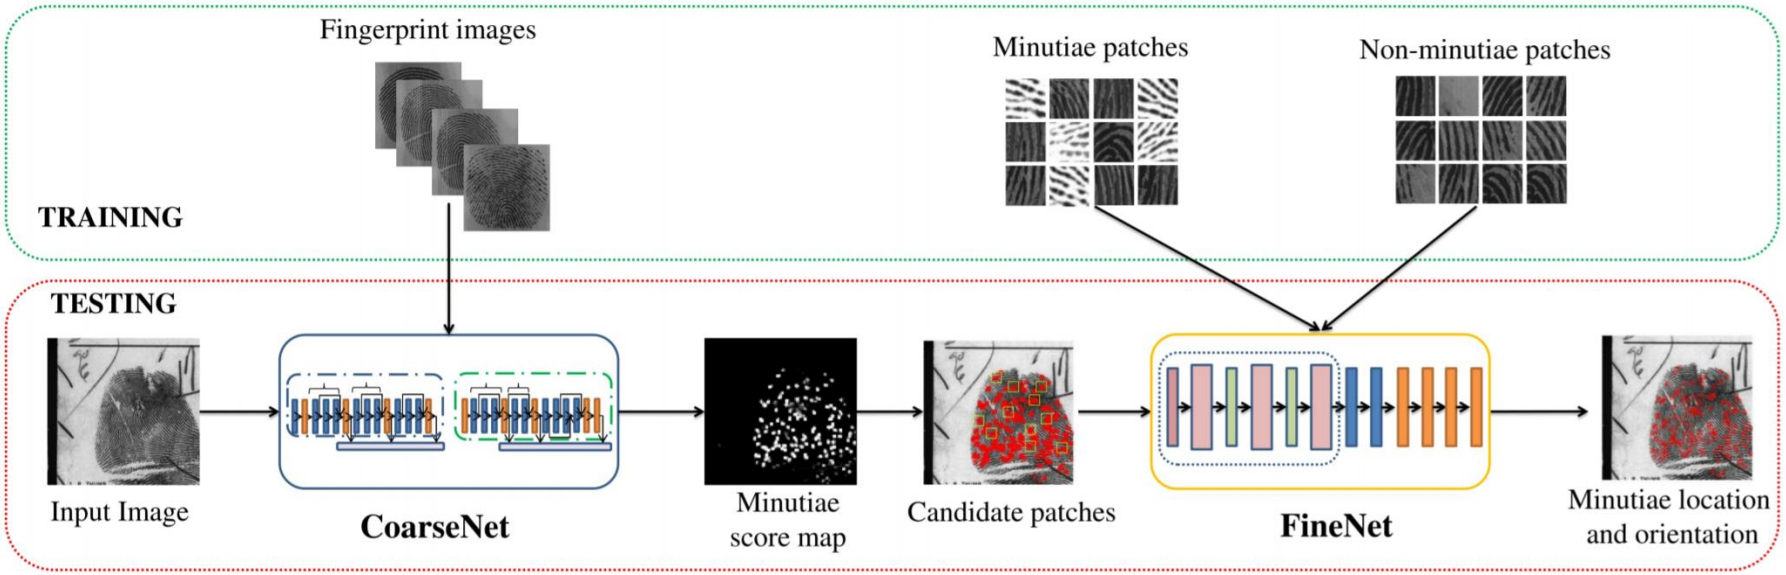


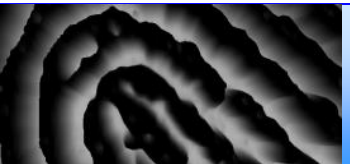


Minutiae Extraction with CNN

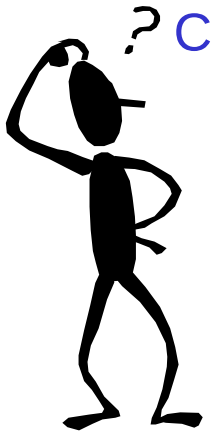
Dinh-Luan Nguyen, Kai Cao, Anil K. Jain, “Robust Minutiae Extractor: Integrating Deep Networks and Fingerprint Domain Knowledge”, ICB 2018.

- Classification of many patches is slow
- Object detection is not appropriate for minutiae patches
- Segmentation + Fine Classification is a smart approach



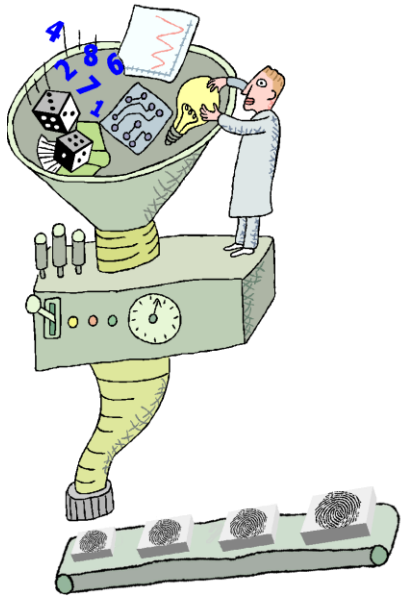


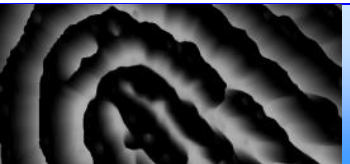
Synthetic fingerprint generation



- Collecting large databases of fingerprint images is:
  - expensive both in terms of money and time
  - boring for both the people involved and for the volunteers, which are usually submitted to several acquisition sessions at different dates
  - problematic due to the privacy legislation which protects such personal data

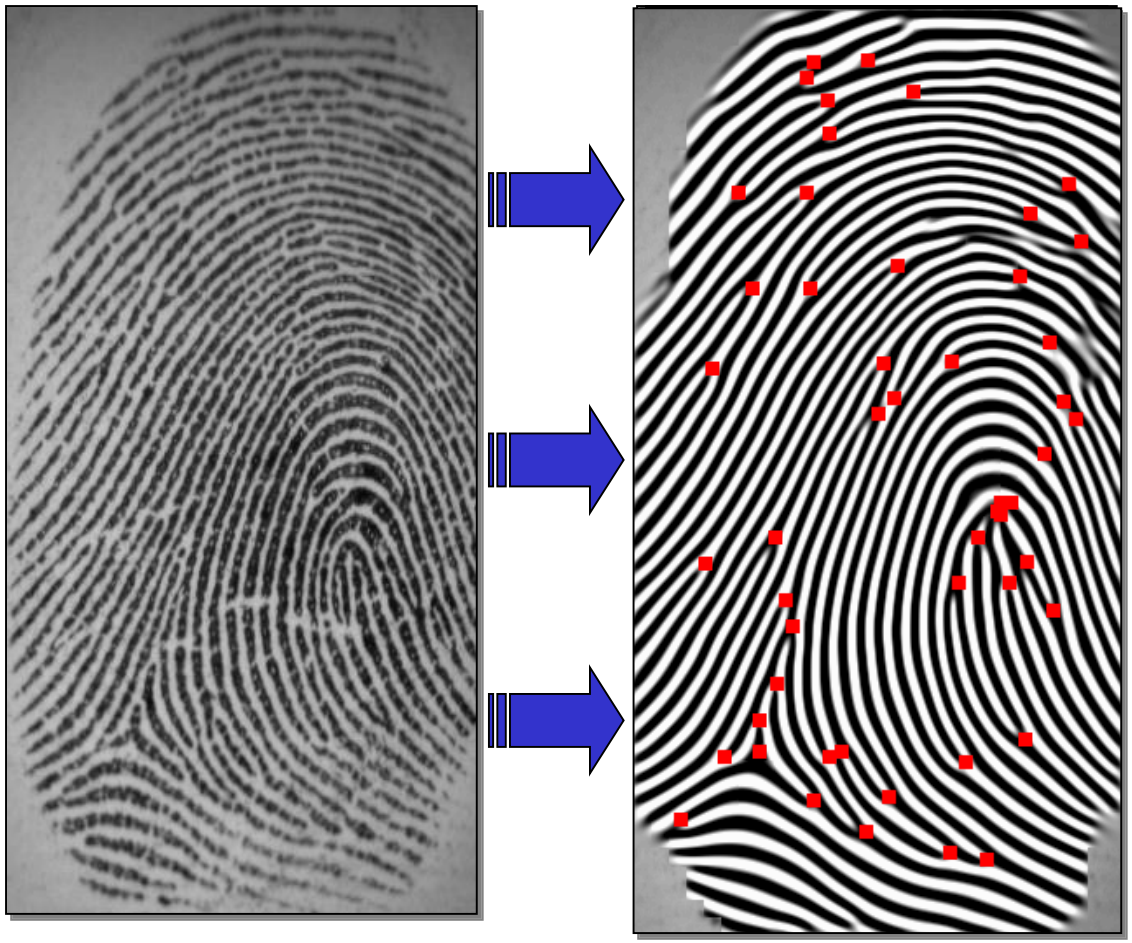
A method able to *artificially* generate realistic fingerprint-images could be used in several contexts to avoid collecting databases of real fingerprints

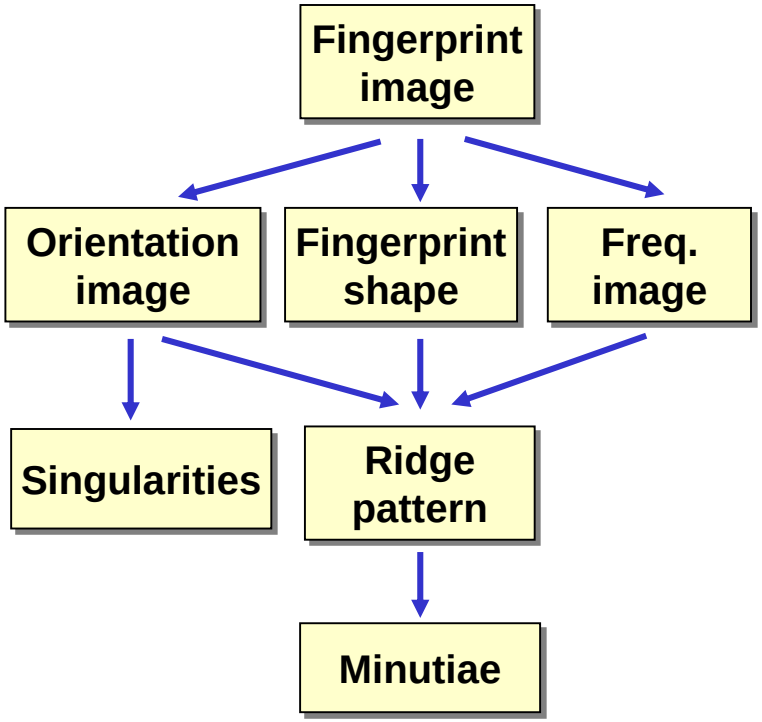


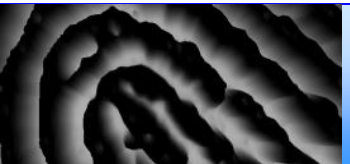


How SFinGe works (1)

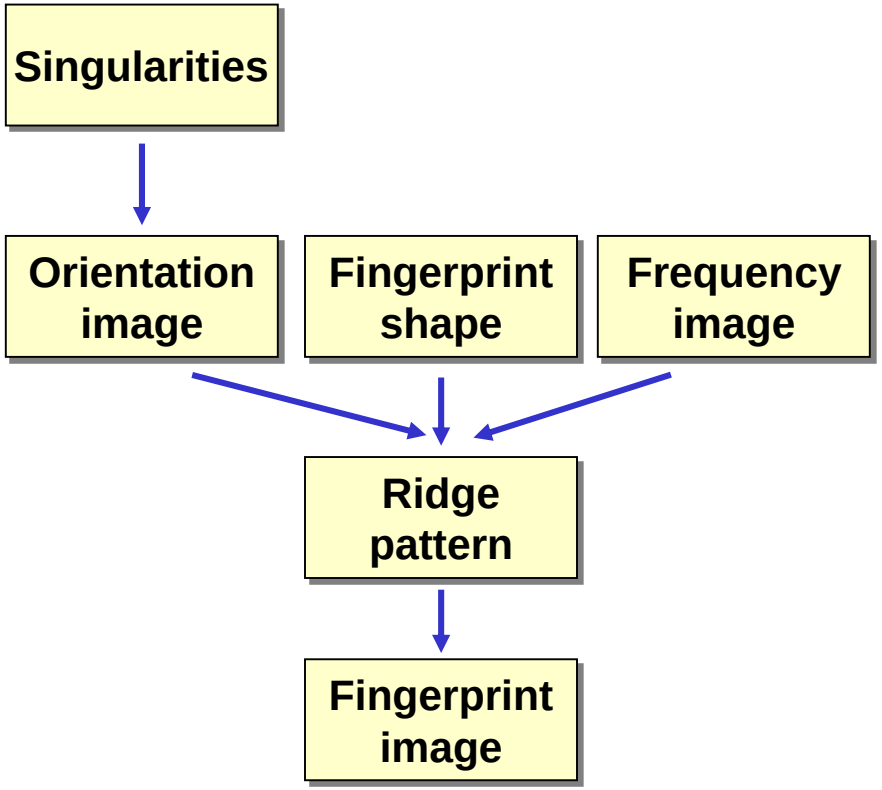
Typical feature extraction from a real fingerprint

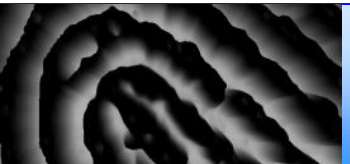




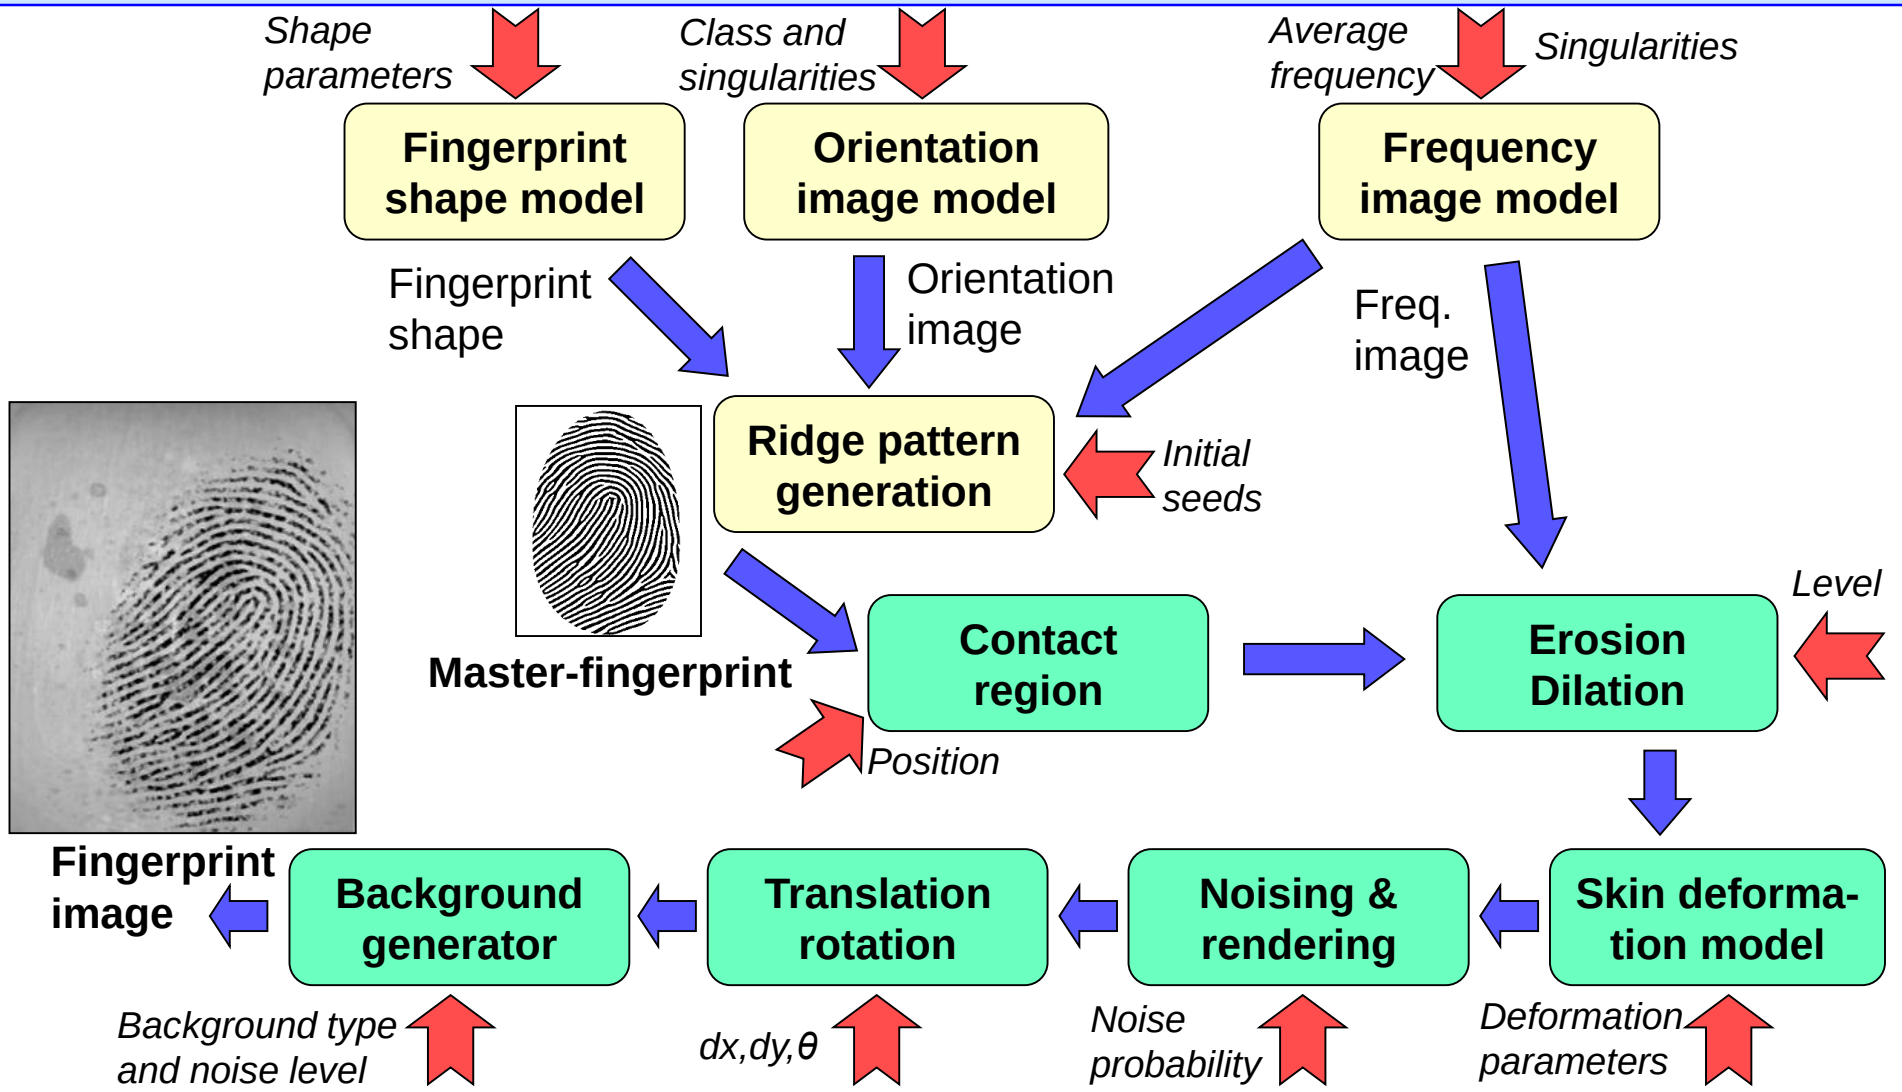


How SFinGe works (2)





How SFinGe works (3)

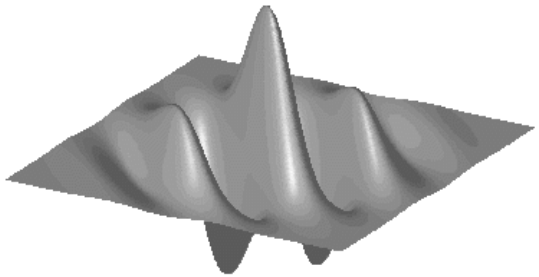


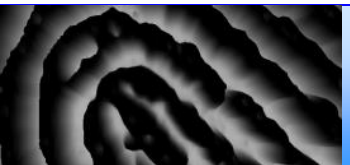
Ridge pattern generation

Gabor-like filters are iteratively applied to an initially-white image, enriched with few random points.

The filters orientation and frequency are locally adjusted according to the orientation and frequency images.

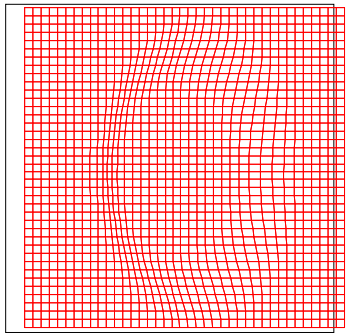
Realistic minutiae appear at random positions

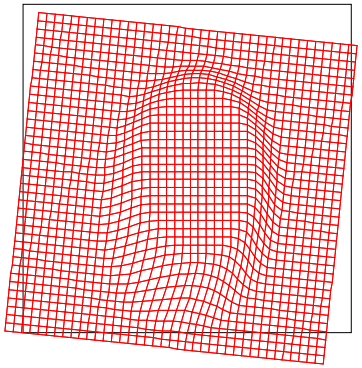


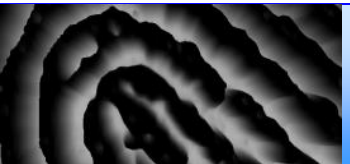


Simulating skin distortion

The skin distortion model is applied to randomly generate realistic impressions of the same “synthetic finger”





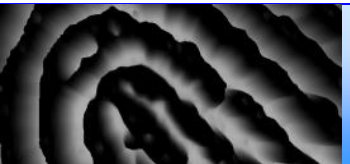


Noising and rendering

Several factors contribute to deteriorate the quality of real fingerprints:

- irregularity of the ridges and their different contact with the sensor surface
- small cuts or abrasions on the fingertip
- presence of small pores within the ridges

SFinGe adds specific noise and applies an ad-hoc smoothing process to simulate real-fingerprints irregularities



Examples

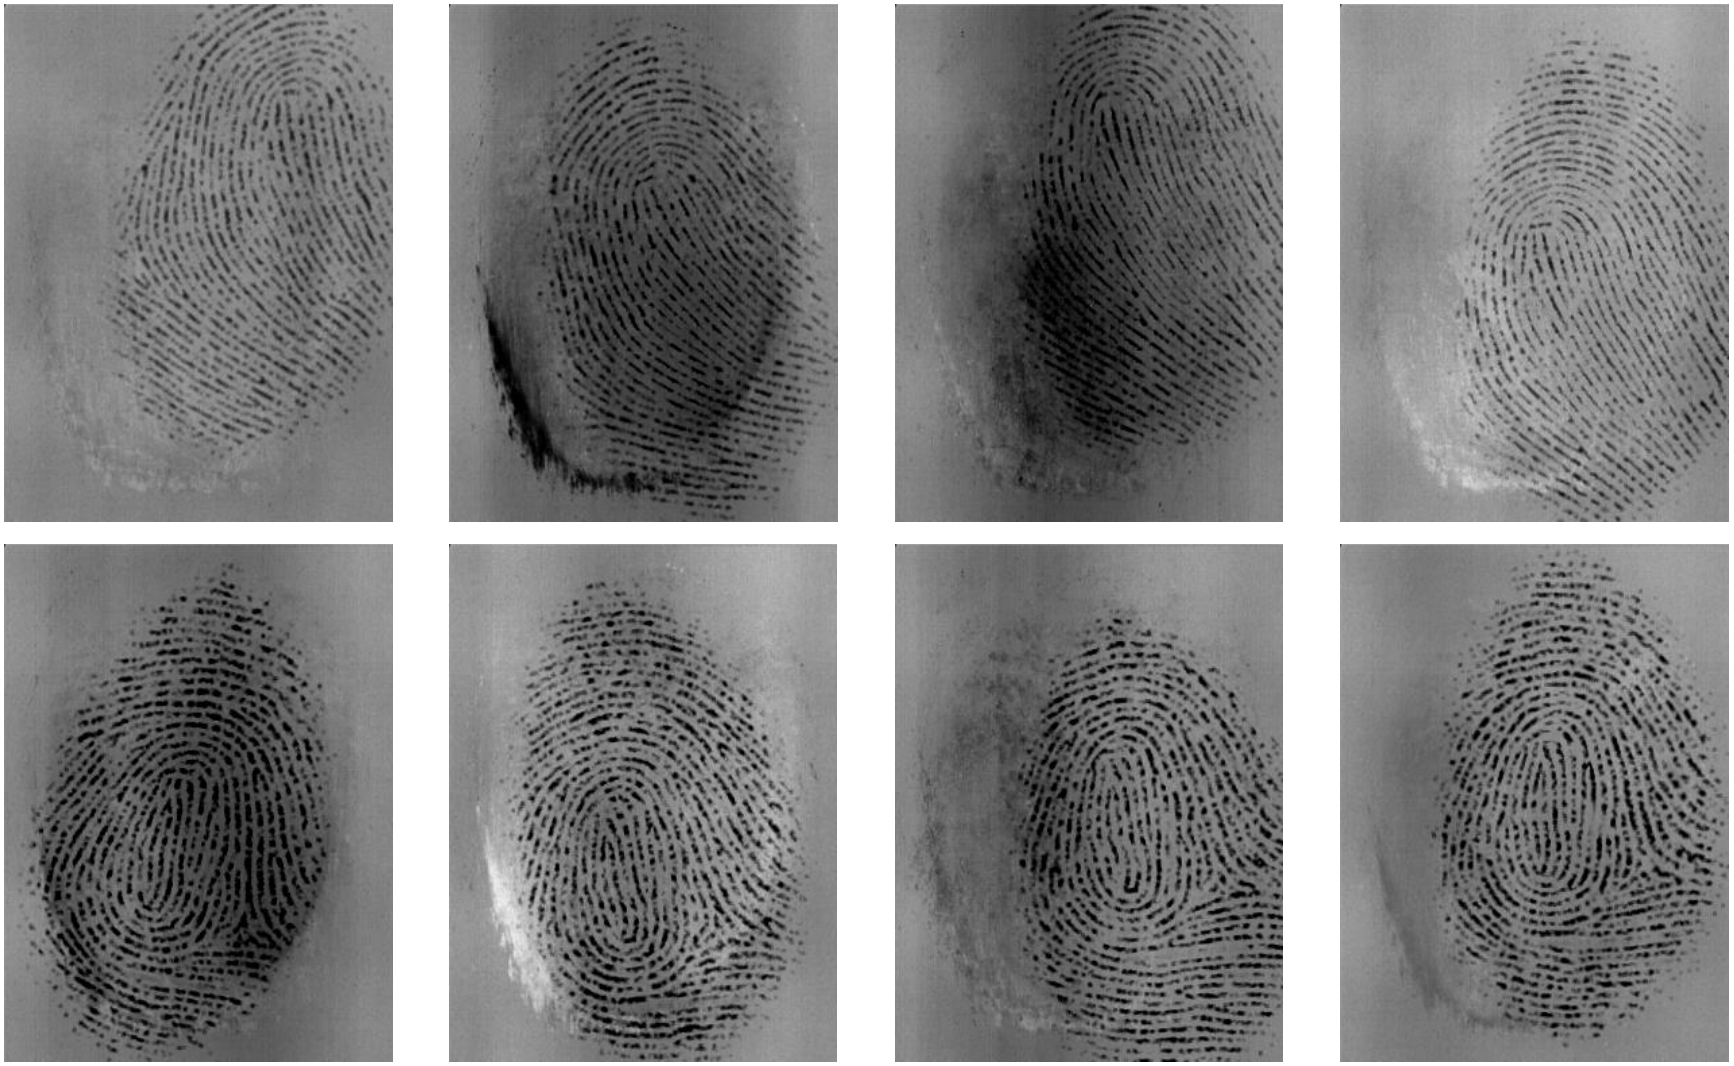
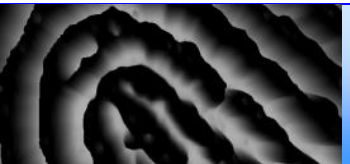
Examples (2)

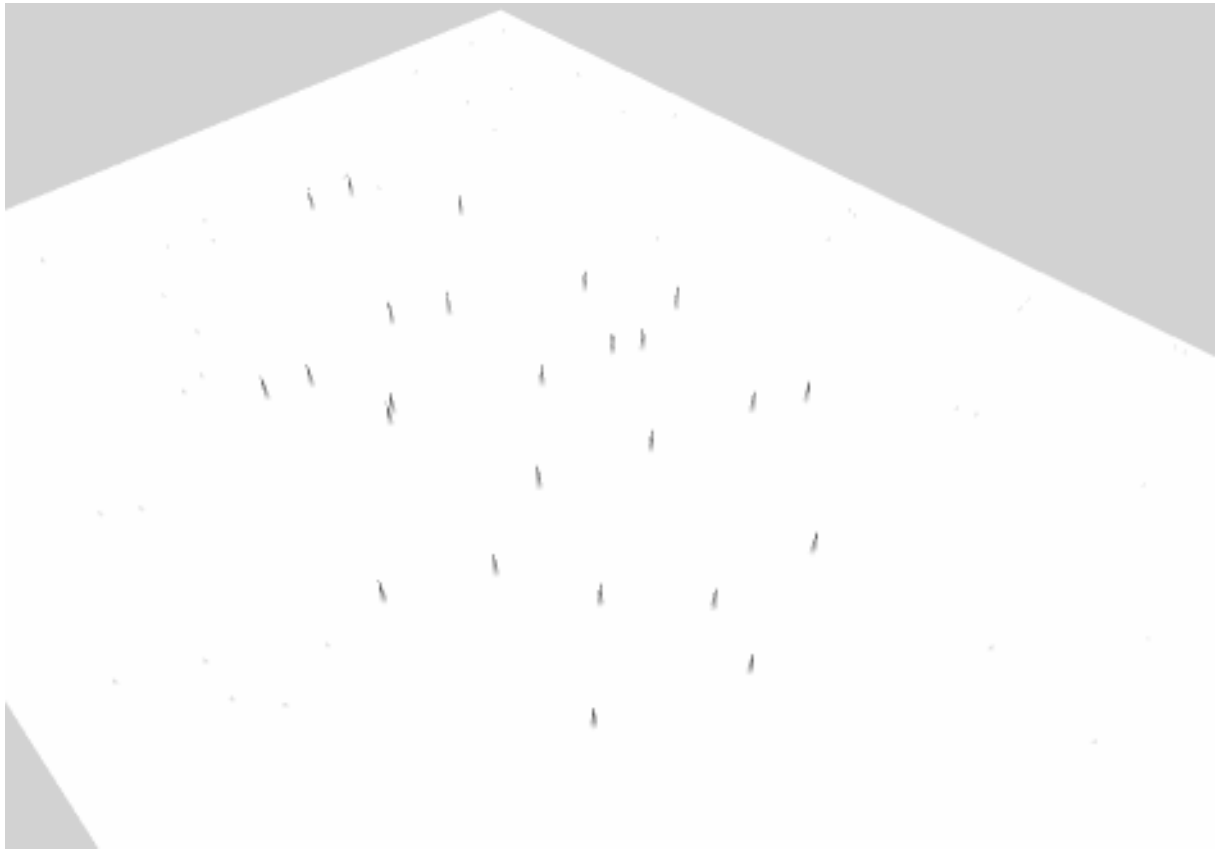


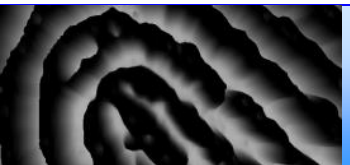


SFinGe: generation of minutiae ground-truth

SfinGe “master fingerprints” are “ideal” fingerprint patterns

SfinGe “master fingerprints” are well-suited for applying the precise minutiae extraction procedures that are being proposed as ANSI and ISO standards.





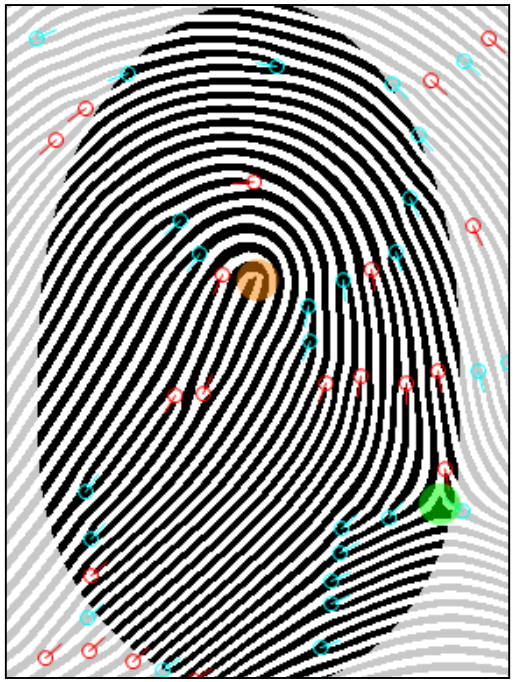
Automatic generation of the *ground-truth*

Master-fingerprint

SFinGe impression-generation steps

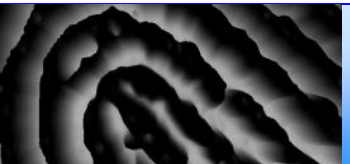
Fingerprint image

Standard-compliant *feature extraction*



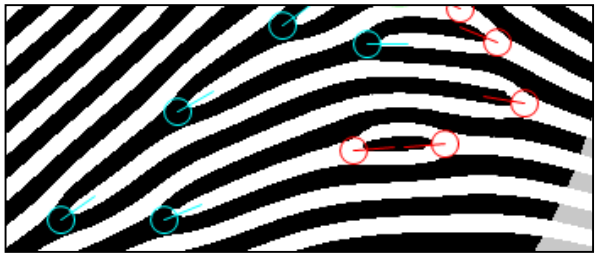
Master-fingerprint minutiae

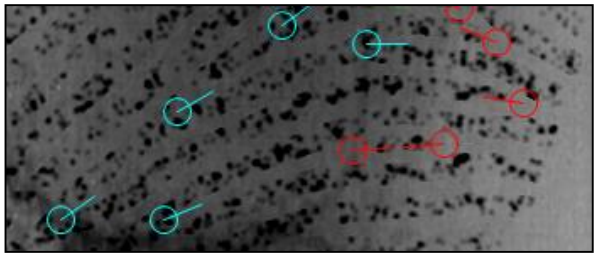
Ground-truth minutiae

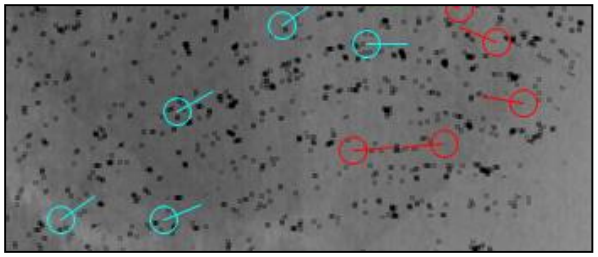


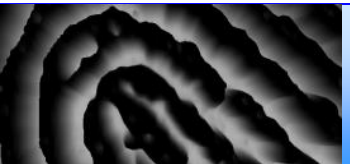
Advantages of SFinGe minutiae ground-truth

- Automatic generation of large fingerprint databases with ground-truth minutiae
  - Features can be extracted by applying the standard procedures easily and without ambiguities (extraction occurs on a binary image without noise)
- The main fingerprint characteristics can be controlled
  - e.g. Fingerprint class, ridge line density, finger placement, skin distortion, fingerprint quality, ...
  - Datasets to test the impact of a given parameter (e.g. fingerprint quality) can be easily generated
- The ground truth is always unique and sound, even when the quality of the final image is very low









SFinGe validation (1)

Fingerprint images generated by SFinGe appear very realistic

About 90 people (many of them having a good background in fingerprint analysis) have been asked to find a synthetic fingerprint image among 4 images (3 of which were real fingerprints).
The synthetic image proved to be not distinguishable from the others

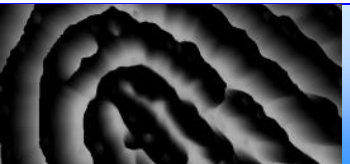
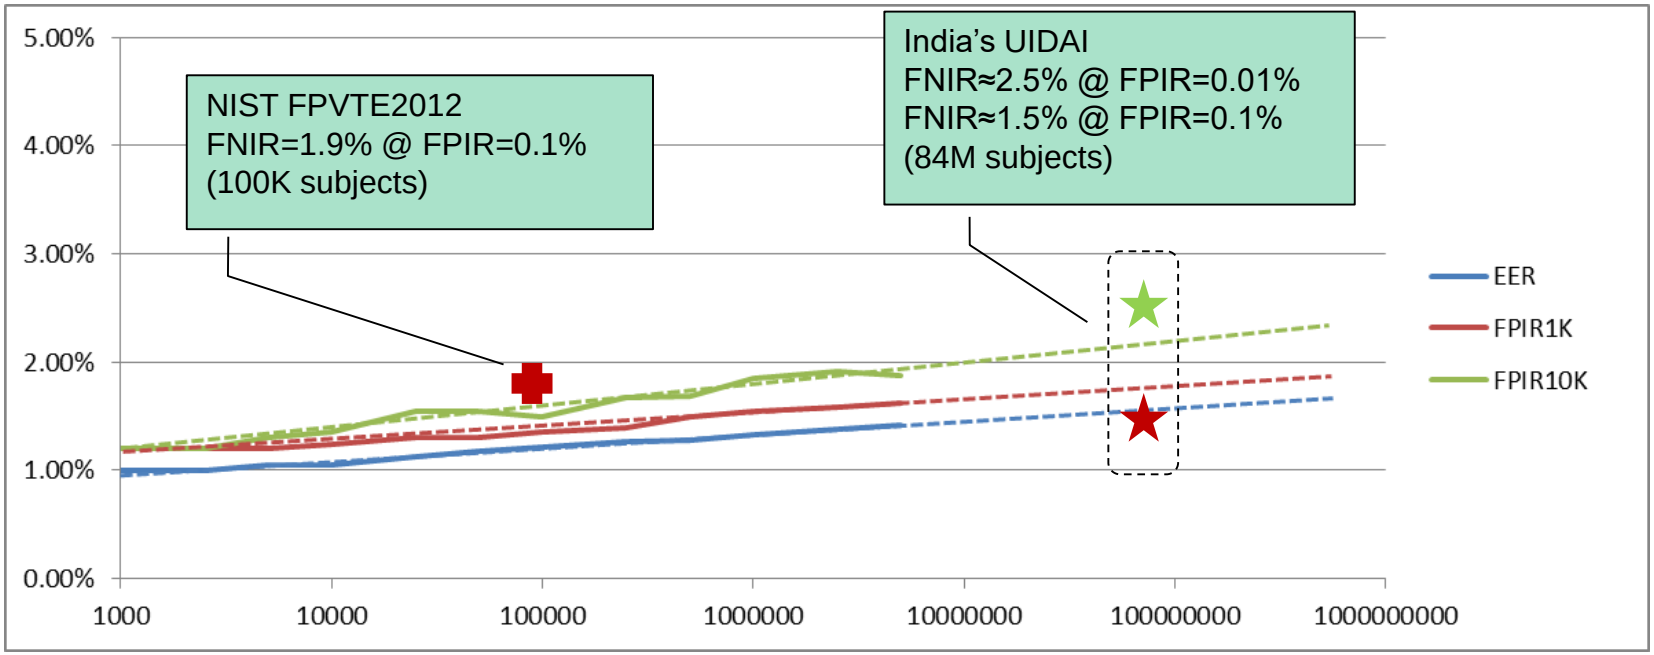
Poll results	
A	23%
B	27%
C	21%
D	29%



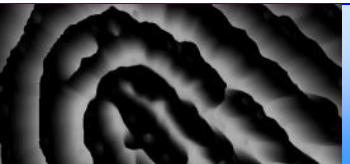
SFinGe validation (2)

Predicting fingerprint identification accuracy with synthetic data [Fidelity Project – EU]

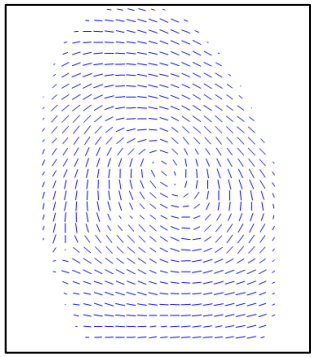


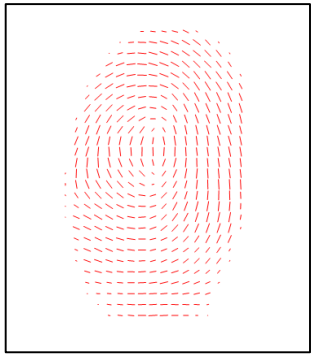
20K queries (10K mates, 10K non-mates)

For this experiment: ≈ 200 billion fingerprint comparisons (carried out on a single PC in less than 11 hours, thanks to other Fidelity developments)



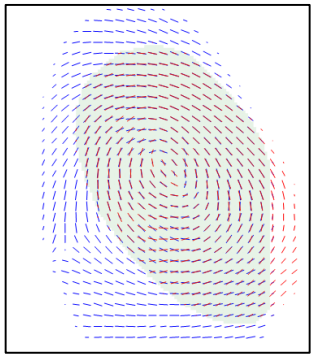
Double identify fingerprints: creation





1. Fingerprint selection

2. Local orientations



3. Best alignment

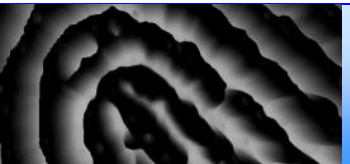
4. Fingerprint superimposition

5. Optimal cutline

Feature-level

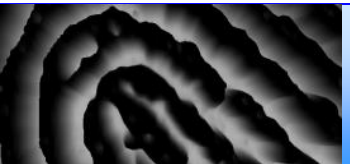
Image-level

6. Fingerprint generation



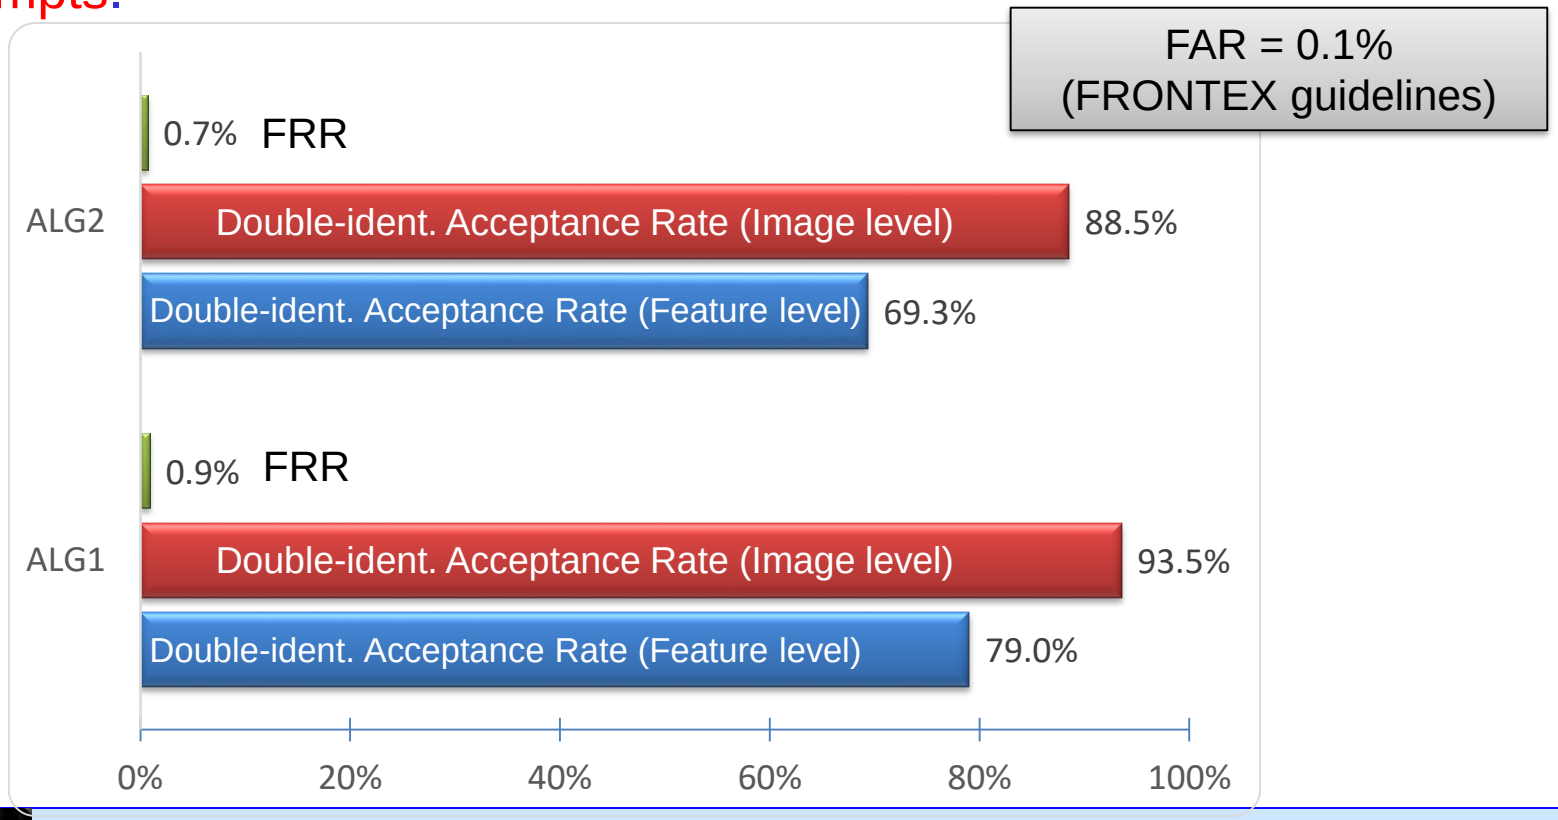
Double identify fingerprints: examples

Fingerprint 1 | Fingerprint 2 | Feature-level | Image-level



Double identity fingerprints

Experiments have been conducted by using two state-of-the-art fingerprint recognition algorithms on the FVC2002 DB1A database, containing 800 fingerprints from 100 fingers (8 impressions per finger) by performing 1400 attack attempts.



Handbook of Fingerprint Recognition

- The book includes results of BioLab research and provides an updated snapshot of the current state-of-the-art in fingerprint recognition.
- More details on the topics of this lecture can be found in this book.

The second edition (a major update) has been published by Springer in 2009
